**ÆSCULAPIAN SOCIETY OF LONDON.**—A meeting of this society was held on Oct. 18th, the President, Dr. Arthur T. Davies, being in the chair. Dr. H. P. Miller showed a specimen of Ruptured Heart from a woman, aged 78 years. There had only been symptoms of "indigestion" until she vomited and fell back dead. The organs were healthy except the heart, which was fatty. The rupture was found at the lower front aspect of the left ventricle.—Mr. Reginald Brown read notes of (1) a case of Wry-neck in a child whose birth was long and difficult; and (2) a case in which a man, aged 45 years, whose liver was to be felt but was not enlarged upwards, complained of pain at and about the liver, had rigors and sweating and a rise of evening temperature to 102° F. He was given potassium iodide with mercury. In a week all symptoms lessened, and in two weeks they had disappeared.—A discussion followed.

**GLASGOW MEDICO-CHIRURGICAL SOCIETY.**—The first meeting of the session of this society took place on Oct. 4th, when Dr. W. G. Dun, the President, delivered an address on Blood-letting in the Treatment of Disease. He gave an historical survey of the whole subject and showed, by quotations from various classical works, how much blood-letting had been abused. The result was that in recent years a reaction had set in, and this method of treatment had been almost entirely abandoned. He maintained that the pendulum had swung too far in this direction and indicated the advantages of its use in conditions where there was sudden engorgement of the systemic veins, pulmonary artery, and especially of the right side of the heart.

## Reviews and Notices of Books.

*Text-book of Medicine.* Edited by GEORGE ALEXANDER GIBSON, M.D., D.Sc., F.R.C.P. Edin., Physician to the Royal Infirmary, Edinburgh. Edinburgh and London: Young J. Pentland. Two volumes, pp. 824 and pp. 869. 1901. Price 25s.

THIS text-book adds one more to the list of those works in medicine not written by a single author, but by several, under the editorship of a physician who himself contributes several articles. This method possesses many advantages as it enables the editor to select those observers who have directed special attention, and it may be research, to those particular subjects upon which they write. There is a danger, however, of such publications being overdone, several having been published in a comparatively short period.

Dr. Gibson may be congratulated on having secured an unusually good number of authors to help him in compiling his text-book. There is scarcely one of them who has not already contributed in a useful manner to medical knowledge and literature. It would be invidious for us to select any one subject for criticism; all are good and their authors have evidently spared no pains to render their own contributions as complete as possible. The plan of including a preliminary discussion of general etiological and pathological problems by way of introduction to the more practical portion of the work is a good one, and an excellent article by Professor G. Sims Woodhead and the late Professor A. A. Kanthack is the result. The reactions of the body and its tissues are first described in the form of cloudy swelling, fatty changes, wasting, and atrophy, necrosis, &c.; also other processes, such as acute and chronic inflammation, regeneration, and repair, are ably described. The remarks on the pathology of bacterial infection will also be found most interesting and instructive. The important matters of infection, predisposition, immunity, toxæmia, &c., are fully discussed.

Another good innovation will be found—namely, that certain symptoms occasionally dignified by the title of separate diseases will be sought for in vain under individual headings, but will be found as parts of the subjects to which they properly belong.

We have already said that it would be invidious to select any one subject for criticism; in a text-book of this size the subjects mentioned are so numerous that to speak in general terms is more satisfactory than to particularise, and this we can do in the highest terms of praise. A notice of the work, however, would not be complete without naming some of the contributors who have assisted in making the book the success which it undoubtedly is; if we do not name all, it is not because the contributions of those whom we omit are less meritorious than the others, but because the number is so great (36 in all) that want of space forbids. Several of the contributors also have written on more than one subject, so that we merely mention their names in connexion with one class of disease. Dr. J. Rose Bradford writes on Diseases of the Kidney, Dr. J. Mitchell Bruce on Diseases of the Endocardium, Sir T. Lauder Brunton on Angina Pectoris, Dr. J. O. Affleck and Dr. C. B. Ker on Typhoid and Other Fevers, Dr. W. Pasteur on Diphtheria, Dr. Patrick Manson on Malaria and Tropical Diseases, Dr. Hector Mackenzie on Tuberculosis, Dr. A. P. Luff on Gout and Acute Rheumatism, Dr. R. T. Williamson on Diabetes, Dr. Thomas Oliver on Lead and Similar Forms of Poisoning, Dr. Sidney Martin on Diseases of the Stomach, Dr. H. P. Hawkins on Diseases of the Intestines, the Editor on Diseases of the Pericardium, Dr. R. W. Philip on Some Diseases of the Lungs, Dr. W. Allan Jamieson on Diseases of the Integumentary System, and amongst those who write on Diseases of the Nervous System are Sir William

Gowers, Dr. Risien Russell, Dr. Alexander Bruce, and Dr. F. W. Mott. There are many other contributors whose articles will doubtless attract equal attention to those that we have mentioned, but we trust that we have said sufficient to indicate the high standard of the work.

*Encyclopædia Medica.* Under the general editorship of CHALMERS WATSON, M.B., M.R.C.P. Edin. Vol. VI., Joints to Liver. Edinburgh: William Green and Sons. 1900. Pp. 562.

THE general standard of the present volume of this encyclopædia is practically the same as that of its predecessors. The main subject dealt with in this volume is Labour, and the 11 articles devoted to it occupy nearly 200 pages. These articles are divided into a physiological section and a pathological section. In the former is contained an account of normal labour and in the latter are considered the various abnormalities which may occur. The Physiology of Labour has been treated by Dr. F. W. Haultain of Edinburgh, and he gives a very clear account of this important subject. The author has acted wisely in giving the measurements of the maternal pelvis and of the foetal head in what may be looked upon as "round numbers" instead of minute fractions; the former are much more easily remembered and are therefore more useful, even though they may not be so accurate; for practical purposes they are of greater value, because the individual normal variations which occur are quite sufficient to impair the trustworthiness of figures founded on averages. Dr. H. Jellett of Dublin has contributed a short section on the Duration and Progress of Labour. The article on the Diagnosis and Mechanism of Labour is from the pen of Dr. W. R. Dakin of St. George's Hospital, and is perhaps the best of the series. It is exceedingly clear and is abundantly illustrated by some clever diagrams which will serve to explain to the reader the by no means simple mechanism of the movements of the foetal head. The account of the management of labour has been undertaken by Mrs. Chalmers Watson, who has described carefully the methods of precaution to be taken in a midwifery case. The article is good and trustworthy. In the list of articles apparently to be provided by the patient is a four-ounce bottle of chloroform. This should surely be brought by the accoucheur. Dr. W. Stephenson of Aberdeen has described Labour in Multiple Pregnancy, and Dr. G. E. Herman, who is curiously called "Obstetric Physician, King's College Hospital," has undertaken the section on Precipitate and Prolonged Labour. This is an excellent article and well illustrated. Dr. W. E. Fothergill of Manchester has written on "Faults in the Passenger," or, as it is more usually described, Labour (Obstructed by Abnormalities in the Ovum. Dr. W. W. H. Tate, of St. Thomas's Hospital, has contributed the section on the Accidental Complications of Labour. Dr. T. W. Eden, of Charing Cross Hospital, has written the article on Retained Placenta and Dr. Jellett that on Post-partum Hæmorrhage. Dr. Jellett advises that in cases of post-partum hæmorrhage which have resisted hot intra-uterine douches the utero-vaginal canal should be plugged with iodoform gauze. The remaining article on Labour is from the pen of Dr. Amand Routh, of Charing Cross Hospital, and deals with injuries during labour.

Articles on the Kidney extend to many pages, but these are occupied chiefly by a paper on the Surgical Affections of this organ by Mr. E. Hurry Fenwick. As might have been expected this is ably written, and especially useful is the list of recent bibliography which is appended to each section of the article. For nephropexy Mr. Fenwick prefers silk sutures.

Another valuable section is concerned with the knee-joint, Mr. Alexis Thomson of Edinburgh describing the diseases and Mr. A. E. Barker of University College, London,

and Dr. E. G. Leopold Goffe of London taking the injuries of the joint. In the account of dislocations of the patella, we find the expression "vertical dislocation" applied to the rotational displacement of the bone on a vertical axis; it is much better called "rotation of the patella on a vertical axis." The other article by Mr. Alexis Thomson on the Surgical Pathology of Joints is of value. In the description of the joint affections of gonorrhœa it is not pointed out that in one, and that the mildest, variety the articular disease appears to depend merely on irritation of the toxins absorbed from the urethra.

Another important series of articles concern the larynx, and of these we may mention especially that on Acute and Chronic Inflammations of the Larynx by Dr. StClair Thomson of London. There are many other articles of interest in the volume that do not need to be more particularly referred to, but we must not omit to notice the very valuable contribution of Dr. H. D. Rolleston on the Diseases of the Liver. It is clear and accurate, and so far as the space allotted has permitted it is complete.

*Report on the Bacteriological Diagnosis and the Antitoxin Serum Treatment of Cases admitted to the Hospitals of the Metropolitan Asylums Board during the Years 1895 and 1896.* By G. SIMS WOODHEAD, M.D. Cantab., Fellow of Trinity Hall and Professor of Pathology, University of Cambridge; formerly Director of the Laboratories of the Royal Colleges of Physicians of London and Surgeons of England. London: Printed for the Metropolitan Asylums Board. Pp. 271. Price 7s. 6d.

THIS most elaborate report is full of interesting matter and the only point for regret is that its appearance has been so long delayed. The report deals exclusively with the cases that were examined bacteriologically during the period between Jan. 1st, 1895, and Dec. 31st, 1896. Owing to overlapping, and in order to bring as many completed cases as possible within the scope of the report, every completed case of which an examination was made during this period has been included, with the result that a few cases appear as having been admitted to hospital during the year 1894, and specimens from cases which were not discharged until the early months of 1897 are included because they were examined in 1896. This plan has enabled the statistics to be somewhat larger than if the calendar year had been strictly adhered to. The large number of cases dealt with enables some definite conclusions to be drawn both as regards the value of the bacteriological diagnosis of diphtheria and the treatment of the disease by antitoxin, and in addition certain side issues are also dealt with.

During the period above described 27,128 cultivations were examined. Of these 24,933 could be traced and assigned to 12,172 patients. Of these cases 73.42 per cent. gave evidence of the presence of diphtheria bacilli, in 5 per cent. of the whole bacteriological examination failed to assist the diagnosis of the disease. This clearly demonstrates the valuable aid afforded by an examination of material removed from the throat in determining the nature of the disease in doubtful cases. Stress is also very rightly laid on the importance of further examination when the first test proves negative; that is to say, in cases which from a clinical point resemble diphtheria, but in which no pathogenic bacilli are found when the usual "swab" has been taken and examined. The reasons for failure are several, e.g., imperfect swabbing of the throat, the use of antiseptics, or the localisation of the bacilli; these must be borne in mind when the cultures yield negative results. The cases of this nature recorded in this report were considerably fewer in 1896 than in 1895, showing that by increased practice in taking the swabs, improved technique, both in preparation of media and microscopical specimens, and further experience in the examination of those specimens, this source of error may be reduced to a minimum.

Another important point referred to is that of mixed infections, especially as regards prognosis. Where diphtheria bacilli only are found the long bacillus appears to be the most active agent in the production of the disease. Mixed infections were proved to be always more fatal than were simple diphtheria intoxications. Contrary to what is usually stated, it was found that the staphylococcus reinforcing the diphtheria bacillus appeared to be associated with a more fatal form of the disease than when a mixture of a streptococcus and the diphtheria bacillus was found. This feature is most marked in the case of the shorter and irregular forms of the diphtheria bacillus and where the long bacilli are absent; in this form of mixed infection the results are much more fatal than are the simple diphtheria infections where the short and irregular bacilli alone are present.

Clearly associated with this matter is the consideration of cases of scarlet fever complicated by diphtheria, and it is interesting to note the fact that in such cases the mortality has been greatly reduced where antitoxin has been used—greatly, no doubt, because of the early period at which the antitoxin is usually administered in these cases.

On turning to the tables of mortality it is seen that this varied greatly at different hospitals, being as high as 27·07 per cent. at the North-Western Hospital and as low as 0·0 at the Gore Farm Hospital, although at the latter place there had been 81 cases, all of which had diphtheria bacilli present in the throat. Further, of the 2503 cases under five years of age in which diphtheria bacilli were found, only 31·52 per cent. proved fatal, as against 47·4 per cent. in the pre-antitoxin period. As regards the percentage mortality where different parts are affected some interesting facts come out. In 1895 where the fauces alone were affected the percentage death-rate was 12·1; where the fauces and nares were affected, 39·5; fauces and larynx, 37·3; the larynx only, 30·7; and where the fauces, larynx, and nares were all affected, 62·2 per cent.; the extent and position of the membrane thus being shown to play a very important part in determining the severity of the disease. In 1896, when the antitoxin had undoubtedly improved and the method of treatment was better understood, there was, as the tables show, a considerable fall in the percentage mortality, especially amongst those cases that must be looked upon as of the most severe type. Another proof of the efficacy of the antitoxin treatment is furnished by the results of those cases which necessitated the performance of tracheotomy. Amongst the 3042 cases in the pre-antitoxin year 1894 there were 261 tracheotomies with 184 deaths, a mortality of 70·4 per cent. of the cases operated on. In 1896, when antitoxin was more used, there were only 246 tracheotomies amongst 5068 cases; of these only 104 patients died, or 41·46 per cent. As Professor Woodhead points out, had tracheotomy been necessary in the same proportion of cases in 1896 as in 1894, there would have been 467·7 instead of 246; or with the same percentage death-rate 328·7 instead of 104, the saving of life in one year on tracheotomy cases alone amounting on this calculation to 225.

There are several other important and interesting matters in reference to the use of the diphtheria antitoxin dealt with in the report, all strongly supporting the success of this method of treatment. This is all the more striking in that a large number of cases are dealt with, making the statistics far more valuable and convincing than when only the results of a few cases are considered.

The second part of the report is devoted to an account of the preparation of diphtheria antitoxin. The method of preparation of diphtheria serum is first described. Then Dr. Cartwright Wood's more rapid and safer method of producing antitoxin is detailed. The technique employed in injecting the horses, collecting the blood, and separating and distributing the serum is duly given. Further we find

described the principles and methods of testing the potency of anti-diphtherial or diphtherial antitoxic serum and, in tabular form, the amount of antitoxin supplied to the hospitals under the management of the Metropolitan Asylums Board.

In the appendix are given in tabular form the details from which the collective tables in the earlier part of the report are compiled. The labour involved in the preparation of this volume must have been immense, and Professor Woodhead and those who assisted him may be congratulated on having issued a work which will accentuate and encourage the general use of one of the most valuable and successful therapeutic measures of modern times.

#### LIBRARY TABLE.

*Proceedings of the New York Pathological Society for the Years 1899 and 1900.* New York: Printed for the Society. 1901. Pp. 347.—Of the numerous and varied communications forming this volume the following may be selected as a few illustrative examples:—Addison's Disease with Simple Atrophy of the Adrenal Body (Dr. Carlin Phillips); a Case of Weil's Disease, with a Short Experimental Study of Infective Icterus (Dr. Harlow Brooks); a Male Pseudo-hermaphrodite (Dr. F. S. Mathews); Miliary Tuberculosis of the Pleura without other Tuberculous Involvement of the Lung (Dr. Eugene Hodenpyl); Carcinoma Gelatinosum of the Mamma and other Organs (Dr. Hodenpyl and Dr. J. H. Larkin); Neuron Retraction (Mr. Frank and Mr. Weil); Mucinæmia (Dr. Isaac Levin); and Sarcoma of the Small Intestine (Dr. E. Libman). Some of the specially chemical or microscopical papers are as follows:—Cases of Gangrenous Bronchitis, with Isolation of an Organism Related to Streptothrix; Puerperal Infection with the Bacillus Aerogenes Capsulatus; Purulent Pneumococcus Meningitis; Changed Appearance of the Diphtheria Bacillus after Four Years' Cultivation; Chemical Examination of a Knife-grinder's Lung; Unusual Cases of Leukæmia; Typhoid Infection of the Uterus; Microscopical Demonstration of "Vaccine Bodies"; Preparation of Hæmatein Staining Solutions; Acid Intoxications; Death from Ether Anæsthesia; and Diabetic Coma. Professor Simon Flexner's "Middleton-Goldsmith" lecture on the Etiology of Tropical Dysentery forms an appendix.

*The Therapeutics of the Röntgen Rays.* By Dr. E. SCHIFF (Vienna). Translated by W. DEANE BUTCHER, M.R.C.S. Eng. London: Rebman, Limited. 1901. Pp. 36. Price 1s.—Hypertrichosis, lupus, and lupus erythematosus are the abnormal or morbid conditions the treatment of which is discussed at most length in this pamphlet. For all three of them Dr. Schiff strongly recommends exposure to the Roentgen rays and gives a variety of particulars as to strength of current, pattern of vacuum-tube, length of exposure, and so on. For hypertrichosis the current in the primary circuit ought to be at most two ampères, with a potential of 12 volts. The distance of the tube is from six to eight inches. Each exposure is of only 10 minutes' duration. The hair often grows again after a period of two or three months, but permanent alopecia is frequently obtained. It is also found that in sycosis the Roentgen rays have a curative effect quite apart from the destruction of the hair. For the treatment of lupus and lupus erythematosus a current of three and a half ampères in the primary circuit is used, with a potential of about 12 volts and a duration of exposure of from 10 to 15 minutes, the tube being at a distance of four inches and the surrounding skin being protected by a mask of stout cardboard covered with sheet lead half a millimetre in thickness.

*Atlas and Epitome of Ophthalmoscopy and Ophthalmoscopic Diagnosis.* By Professor Dr. O. HAAB of Zürich. Authorised

translation from the third revised and enlarged German edition. Edited by G. E. DE SCHWEINITZ, A.M., M.D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia, &c., with 152 Coloured Lithographic Illustrations. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 83. Price 13s.—This work is a translation of one of Lehmann's useful "Medicinische Handatlanten" and the original has been rendered into very good English. A translation by Mr. Ernest Clarke of the first edition of Professor Haab's treatise was reviewed in this journal in 1895. It then contained 39 lithographs, which were for the most part coloured, and were accompanied by 55 pages of letterpress. In this volume before us, which is the translation of the third German edition (recently reviewed in these pages), the number of illustrations has almost doubled and the letterpress has extended to 80 pages. The increase is due in the case of the text to a fuller description of the modes of examining the eye by the direct and indirect methods, to a more exact account of the shadow test, and of pulsation phenomena. In the case of the illustrations those that have been added are in part pathological and in part exhibit the appearances presented by sections of normal structures. The third plate shows a section through the retina, choroid, and sclera near the macula lutea seen under a low power. We should have expected a better plate. It shows the nuclear layers of the retina with quite isolated and independent nuclei. The ganglion cell layer is depicted as it was drawn 40 years ago. There should at least have been a companion plate showing connexions of the cells and nuclei and generally the results of modern research with high power of the microscope. Several additional plates showing forms of albuminuric retinitis have been added in this edition as well as others exhibiting the microscopic lesions. Dr. Schweinitz has himself appended a few figures—namely, those showing angioid streaks in the retina and the ophthalmoscopic appearances seen in arterio-sclerosis—which are well drawn. One of the new illustrations introduced by the author exhibits the appearances presented in syphilitic neuro-retinitis and disease of the retinal arteries. The case shows a stellate figure at the macula, but it is stated that there was not at any time a trace of albumin discoverable in the urine. A good chromo-lithograph is also given of a perforation of the macula lutea after contusion of the eyeball; the perforation has sharply-defined edges, is about half the size of a papilla, and is surrounded by a slightly opaque area, presenting minute dots and in places covered with pale, glistening spots and patches. Professor Haab remarks that openings of this kind at the fovea may appear spontaneously in advanced age without any traumatism, possibly owing to arterio-sclerosis. There is an instructive plate showing an air-bubble in the upper portion of the vitreous due to the entrance of a fragment of iron. We recommend Dr. Schweinitz's translation of the third edition of Professor Haab's Ophthalmoscopic Atlas as a work that should be in the ophthalmic wards or in the library of every hospital into which ophthalmic cases are received. It will be found to be extremely useful as a book of reference.

*Annual Report of the Imperial Bacteriologist for the Year 1900-1901.* Calcutta: Office of the Superintendent of Government Printing. 1901. Pp. 9.—In his report for the year 1900-1901, submitted to the Government of India, Dr. Alfred Lingard, the Imperial bacteriologist, states that during that period the laboratory officials were principally occupied in manufacturing anti-rinderpest serum and despatching it to the superintendents of the civil veterinary department and other officers who demanded it. A protective serum is being made by two methods, one requiring about 80 days for preparation and the other requiring from 14 to 20 days. The propagation of locust disease fungus was

continued and 156 tubes were sent out during the year, but it does not seem to have established its efficacy in India as it did in South Africa. Dr. Lingard has collected material for a second report on lymphangitis epizootica, a disease which was imported by mules from Italy and assumed the epidemic form in India in 1899.

#### JOURNALS AND MAGAZINES.

*The Journal of Anatomy and Physiology.* Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S.; D. J. CUNNINGHAM, M.D., F.R.S.; G. S. HUNTINGTON, M.D.; A. MACALISTER, M.D., F.R.S.; and J. G. M'KENDRICK, M.D., F.R.S. Vol. XXXVI., Part 1. October, 1901. With Plates and Figures in the Text. London: Charles Griffin and Co. 8vo. Pp. 94. Price 6s.—This part contains the Proceedings of the Anatomical Society of Great Britain and Ireland for July, Notes on the Aberdeen University Anatomical Society, and ten articles. Of these the first is a Contribution to the Study of the Morphology of Adipose Tissue, by Dr H. Batty Shaw of University College Hospital. This observer agrees with Flemming that fat cells are modified connective tissue cells. 2. The Structure of the Left Auriculo-ventricular Valve in Birds, by Mr. A. Hodgkinson of Owens College, Manchester. He finds that this valve is formed of three cusps and is therefore of the tricuspid type. 3. On the Development of the Renal Portals, and Fate of the Posterior Cardinal Veins in the Frog, by Dr. Thomas W. Shore, Lecturer on Comparative Anatomy and Biology to St. Bartholomew's Hospital and College. 4. A description of the "Socia Thymi Cervicalis" and Thymus Accessorius, by Dr. N. Bishop Harman. 5. A case of Rudimentary First Thoracic Rib in a Horse, by Dr. O. Charnock Bradley, Professor of Anatomy, Royal Veterinary College, Edinburgh. The condition was symmetrical. 6. A case of Congenital Malformation of the Heart with Abnormalities of the Abdominal Viscera; Absence of the Spleen; Absence of the Hepatic Section of the Inferior Cava, by Dr. T. W. P. Lawrence and Dr. David Nabarro. The case is in many respects interesting and the dissection was carefully made. 7. Two cases of Supernumerary Radialpalmar Muscle, by Dr. Norman W. Kater. 8. A case of Multiple Renal Arteries, by the last-named writer. 9. Description of a Fetus Amorphus, by Dr. George A. Charlton, with three plates. 10. Acardiac Monster caused by a Fetal Adhesion to a Placenta Succenturiata, by Mr. Edred M. Corner, resident assistant surgeon, St. Thomas's Hospital.

*Caledonian Medical Journal.*—Much of the October number is occupied with an account of the twenty-first annual meeting of the Caledonian Medical Society held on August 9th in the Hall of the Faculty of Physicians and Surgeons of Glasgow, Dr. H. Cameron Gillies (London) presiding. At the annual dinner, which took place the same evening, the toast of the Caledonian Medical Society was proposed by Sir Hector Cameron and acknowledged by Dr. Gillies. The society has 180 members. The Gunning Celtic prizes of the society, to be awarded next year, have been several times mentioned in THE LANCET; it is now announced that another prize of £10 will be competed for after the award of the Gunning prizes has been made. Dr. D. G. Sutherland of Brora, Sutherlandshire, contributes to the journal an article on surnames in that county. Mackay is the most frequent one, being borne by 20 per cent. of the population; next in numerical order is Sutherland, with 8.5 per cent.

*Birmingham Medical Review.*—In the October number Dr. W. A. Potts writes on Mentally Deficient Children with especial reference to the early diagnosis of the condition in question. Dr. T. Stacey Wilson describes the various Displacements of the Heart, classifying them as due either to changes within the heart itself, or to alterations in the

volume of the lungs or of the abdominal organs, or to the growth of tumours.

*Journal de Mal de Mer et de la Santé à bord des Navires.*—Paris: 82, Boulevard Port-Royal.—In the August-September number of this periodical, which is the journal of the League against Sea-sickness, Dr. Zahé advances the argument that slight degrees of umbilical hernia are more common than is generally supposed and that a predisposition to sea-sickness is thereby created. For the relief of sea-sickness attended by this complication he has devised a sort of compress, called the "contentif ombilical." Dr. Maggioranni of Rome writes recommending the hydro-electric bath.

## New Inventions.

### ELECTRICAL EVAPORATING AND INHALING APPARATUS.

It is claimed for the evaporating and inhaling apparatus shown in the accompanying illustration that it may be used even by a patient lying in bed without danger of fire or explosion, the source of heat being a small electric lamp. The vapour employed can be inhaled through either the mouth or the nose with the help of the indiarubber nozzles sent with the apparatus, or it can be blown into the ear by means of a double bellows. The drugs capable of being inhaled in this way include oil of turpentine, oil of eucalyptus, alcoholic solutions of menthol, thymol, creasote, guaiacal, carbolic acid, &c. The prescribed number of drops are allowed to fall on wadding contained in the upper part of the inhaler. The apparatus is then connected with a source of electric current, such as a wall-plug or lamp-holder, or an accumulator if electricity is not laid on to the house. When the incandescent lamp is alight the patient may begin to inhale. The maker is Mr. K. Schall, 55, Wigmore-street, W. The apparatus in its ordinary form is designed for a tension of 110 volts. If tensions much exceeding this are to be employed a statement to that effect should accompany the order.

### A DISINFECTING CLOTH FOR TELEPHONES, SPEAKING-TUBES, &c.

THAT telephones and speaking-tubes may easily become sources of infection is obvious, and the "odourless retentive disinfecting cloth" is designed to avoid this risk. According to our analysis the fabric contains two distinct chemical salts, one of which, being hygroscopic, serves to keep the cloth permanently moist and the other to render it germicidal. In a word, the cloth is an antiseptic wiper, as shown by a number of bacteriological experiments made with it. Our experiments have shown that the cloth keeps moist practically indefinitely, a very important point. The cloth is replaced at intervals by the company supplying it for a small annual payment. Disinfecting tests have been made with it by purposely infecting the transmitter and receiver of a telephone with cultures of disease germs. It is stated that on the average 98.70 per cent. of the germs were removed, and, further, that the microbes on the cloth were found to be destroyed. In this way the pus organism, the typhoid organism, and faecal organisms were employed for the experiment. There is no doubt that the cloth might be employed with special advantage in public call offices. It may also be used for other purposes, such as for cleaning surgical instruments, for wiping Bibles in police-courts where

the objectionable system of kissing the book still prevails, for wiping razors, for cleansing the seats of water-closets, and countless other uses and applications. The specimen which we examined was submitted to us by the Odourless Retentive Disinfecting Cloth Company, of 96, Leadenhall-street, London, E.C.

### A MEAT JUICE EXTRACTOR.

THE accompanying illustration easily explains the construction of this very useful beef press which is intended chiefly for use in the patient's own home. The interior consists of a strong metal cup provided with perforations. Into this cup and nearly fitting it a similarly strong cup, made also of metal, is forced downwards

by means of a screw and handle similar to that of the copying press. The pressing cup is deeply grooved in a diagonal direction. The surfaces of both cups are galvanised and are clean and bright. The apparatus works excellently and economically. It is a great advantage for the patient to have beef juice prepared freshly at his own home, and, moreover, his medical adviser is thus enabled to prescribe exact allowances. Of course, mere pressure does not extract by any means the entire nutritious portion of beef; still, a juice is obtained in this apparatus of a powerful, nourishing, and stimulating quality.

Obviously the extracted meat or residue may also be used if desired. The apparatus is well adapted for both hospital and home use and is very convenient. It may be obtained from the Alexander Manufacturing Co., of 42 and 44, Moor-lane, London, E.C.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Oct. 17th, Mr. H. G. Howse, the President, being in the chair.

A letter was read from the Secretary of State for Home Affairs reporting the very gracious reception by His Majesty the King of the address of condolence from the Council of the College on the death of the Dowager Empress Frederick of Germany.

Mr. HOWARD MARSH reported that in accordance with the wishes of the Council he had attended the celebration of Professor Virchow's eightieth birthday at Berlin on Oct. 12th and had presented to him on behalf of the Council an address of congratulation. It was resolved that the address should be entered on the minutes, and the best thanks of the Council were given to Mr. Marsh for acting as the delegate of the College.

Mr. R. HARRISON, on behalf of the Committee on the Annual Report of the Council, submitted a draft copy of the report to be presented to the Fellows and Members at the annual meeting to be held on Nov. 21st, 1901.

Sir William MacCormac, Bart., was re-elected a member of the Committee of Management.

Mr. H. T. Butlin was elected a member of the Laboratories Committee in the vacancy occasioned by the retirement of Mr. H. G. Howse.

A letter was read from the Privy Council, inclosing a copy of a note from the Egyptian Acting Minister for Foreign Affairs, announcing that a medical congress will be held at Cairo from Dec. 10th to 14th, 1902, and on behalf of the Egyptian Government expressing a hope that British scientific societies and institutions will take part in the congress.

A letter was read from the President and Secretary of the Fourteenth International Medical Congress, asking the President of the College to announce that the Congress will be held at Madrid from April 23rd to 30th, 1903, and inclosing copies of the rules of the Congress and forms of application for membership.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 26, 1901.

## School Punishments.

No animal when young likes being taught, and therefore some measures of discipline are found to be a necessity. Discipline includes punishment, and one form of punishment is that known as corporal, involving the infliction of pain. We have always maintained that corporal punishment is the best form for certain offences, notably for that form of brutality known as "Hooliganism," a word which includes attacks upon the police or upon old men or women with or without the additional crime of robbery. We should also like to see the punishment of flogging extended so as to cover criminal assaults upon children or gross cases of cruelty to lower animals. But the matter with which we are more immediately concerned at present is corporal punishment as used in schools, whether in great public schools, in national schools, or in board schools, and as an instance of what corporal punishment as used in a school should *not* be we cite the following account as forwarded to us by a correspondent. He tells us that his son, aged 11 years, a day boy at a large public school, returned home one day with his hands severely bruised on account of a caning received from the head-master. The boy's hands were covered with weals and there were extravasations of blood under the skin. So severe were the injuries that the boy was unable to use pen or pencil for some days.

The object of all school punishments should be to deter as well as to reform, and they may be divided into expulsion, corporal punishment (caning or birching); and impositions. Of the first class of punishment we shall say nothing here. With regard to the second we think it both necessary and useful. But when administered it should be a reality and not used as it was at Westminster in BUSBY'S time or at Eton under KEATE as a punishment for great offences and trivial misdemeanours indiscriminately. With regard to the instrument by which the punishment is inflicted it is either the cane or the birch, and in our opinion the cane should never be used as the ordinary instrument of school punishment. A cane may possibly bring about irreparable damage, and caning on the hands is the most senseless and cruel form of punishment imaginable. The hand is a delicate and wonderful piece of anatomy, its nerve endings and the muscles which bring about the finer movements are but imperfectly protected from blows, and to produce injuries such as those described by our correspondent would be wrong even in reply to the worst of schoolboy offences. The birch is the best implement of punishment for small boys. Firstly, it hurts; secondly, if applied in reason it does no harm; and, thirdly, the seat of election for a birching is the gluteal region and this from its anatomical construction is fitted for the reception of corporal punishment. The skin over it is thick and

plentifully supplied with nerves so that the desired pain is easily felt without the infliction of violence. There is underneath the skin a good layer of fat, underneath this again is a layer of thick coarse-fibred muscles, upon which follow the bones protecting the parts within the pelvic cavity. But while we defend corporal punishment in certain cases, we consider that there are rules which should govern its infliction. In the first place it should never be inflicted by an under-master, but only by the head-master, or someone to whom the head-master delegates his penal authority. This plan practically necessitates the existence of the second rule—namely, that corporal punishment should never be inflicted immediately upon the commission of the offence, and also it allows opportunity for appeal. Thirdly, it should be reserved for offences of some magnitude and should be fairly severe. The birch is the best instrument and it should be applied to the buttocks.

The idiotic custom of setting lines is a futile form of punishment. True, it keeps a boy from his play, or, what is worse, prevents him from doing work which might be useful to him, but as a punishment it does not do the slightest good and leads to habits of deceit. We have probably most of us written out, say, 500 lines, scribbled off as fast as possible, with two or even three pens at a time, knowing perfectly well that the master would never count them and would probably just glance at them. An imposition should be of some use, and to set a boy a copy of verses or a piece of prose composition would be infinitely more serviceable. Punishment is a necessity, but it should be inflicted in a reasonable manner, and corporal punishment, if safeguarded, as we have endeavoured to show, is a penal method by no means to be lightly given up. It is, we fancy, not nearly so much resorted to nowadays as it was even so lately as 30 years ago, and our readers should remember that all of them can at times add the weight of their professional opinion to the protests of parents in a case such as we have cited above: while such of them as are medical officers of schools can raise their voices against the use of the cane in any way, and caning on the hands should be absolutely interdicted.

## Ophthalmoscopy Applied to the Eyes of Mammals.

A HIGHLY creditable memoir, the fruit of many years of quiet and unobtrusive research, has just been published in the Philosophical Transactions of the Royal Society. It is written by Mr. GEORGE LINDSAY JOHNSON and is devoted to the description and illustration of the ophthalmoscopic appearance of the eyes of many animals. A few, but very few, works have been published on this subject. The eyes of the ordinary domestic animals have of course been examined by many veterinary surgeons, but even of these scarcely any coloured plates are extant, and the inquirer has to be content with verbal descriptions. Mr. JOHNSON'S 29 plates, with more than 60 figures, are a revelation in this department of ophthalmology. They are beautifully executed by Mr. ARTHUR W. HEAD and have been extremely well chromo-lithographed. 182 mammals have been examined, falling under 103 genera, and 47 families representing all

the natural orders of this class, with the exception of the cetacea and sirenia. The colour of the fundus oculi in those animals that have no tapetum is chiefly due to the reflection of light by the choroidal pigment. In the carnivores, which have a cellular tapetum, it is mainly determined by the colour of the retinal pigment, whilst in the ungulates, which have a fibrous tapetum, it is due to the colour of the tapetum modified by the colour of the retinal pigment. Examples of the different colour presented by the fundus may be seen in man and in nearly all the primates, in the suidæ, in the hyracoidæ and in the rhinoceros, in which it is of the red type; a yellow fundus is seen in the chiroptera, in some felidæ and mustelidæ, in the elephant and in the tapir; and lastly, a green and yellow-green type of colour is met with in most carnivora and in all selenodonta except goats and camels. These varieties are beautifully shown in the plates. The drawings were obtained by the direct method of using the ophthalmoscope, which would at first sight seem impossible to apply to wild animals, since it involves the close approximation of the eye of the observer to that of the animal under observation; but Mr. JOHNSON observes that, as a rule, kindness, coaxing, and taming were sufficient to overcome all difficulties. The lids were held apart with the fingers or spring specula and mydriatics were generally employed. When we find elaborate drawings of various monkeys and lemurs, of the seal, the serval, the skunk, the black bear, the camel, the wild boar, the Indian rhinoceros, the tapir, the elephant, and many others, we are at a loss whether to admire most Mr. JOHNSON'S courage in patiently watching his opportunity to examine the eyes of these formidable animals, which could not have been subjected to any anæsthetic, or the very curious, interesting, and instructive drawings which he has obtained.

The disposition of the choroidal vessels is seen to vary greatly. In some instances they are very conspicuous, as in the Indian rhinoceros and the elephant, the kangaroo, the wombat, the beaver, and the chinchilla, the meshes being sometimes fine and close, at others coarse with wide areolæ; sometimes, on the other hand, they are wholly invisible, as in the hairy armadillo, the British black rat, and the hedgehog. The optic disc, again, presents great differences in form, size, and colour, being sometimes circular, as in man, the chinchilla, the beaver, and many others; sometimes oval, with the long axis vertical, as in the echidna; or horizontal, as in all the equidæ, the carnivore *cynictis*, the wild boar, the hog-deer, and the chevrotain; sometimes with large retinal vessels springing from near its centre; and sometimes with numerous small vessels emerging at, and radiating from, its periphery, as in Burchell's zebra. Sometimes it is of a dead white colour with no visible vessels, as in the Indian rhinoceros and the perissodactyls generally, the hairy armadillo, and the echidna; or grey without vessels, as in the Brazilian porcupine; or with a small closed plexus, as in the rabbit-eared perameles, the squirrel-like phalanger, and the rufous rat-kangaroo. In the striped hyæna—not perhaps the most engaging of animals to examine—in the black-backed jackal, and in the black bear it is of a deep red hue, whilst in others, as the chevrotain and the hog-deer, it seems to be permeated with pigment. The different appearances of the tapetum with its yellowish-green tint and

brown or black borders are beautifully portrayed. It is exceedingly interesting to find that Mr. JOHNSON has observed in certain animals as normal conditions appearances which in man are regarded as congenital defects or vestigial relics. Thus opaque nerve-fibres are very marked in some of the rodents and marsupials. Nearly all of the cat tribe and the flying squirrels present a physiological cup in the disc. A condition resembling retinitis pigmentosa is seen in the galagos and the lorides, and it is remarkable that if these nocturnal animals are long exposed to daylight the pigment advances concentrically as in the retinitis pigmentosa of man, and the animals gradually lose their vision. A persistent hyaline artery which is occasionally seen in man is found as a normal condition in nearly all the ruminants and in a large number of the rodents. Some of the rodents, and more especially all the agoutis, present vestiges of a pecten.

The presence of nerve-fibres with retained sheaths giving a radiated aspect to the disc is of common occurrence, being seen in the skunk, in the squirrel, and in the rabbit. As a good ophthalmologist Mr. JOHNSON has not confined his attention to the aspect of the fundus, but has made some observations on the refraction of many animals, and finds that with the exception of the seals and whales vision is hypermetropic throughout the mammalia. The seals are astigmatic to an extraordinary extent—a condition that is probably connected with their amphibious life. Domestication appears in the eye, as in other organs, to increase variability, the colour of the fundus as well as the refraction undergoing marked alterations in such animals as the dog, the horse, and the rabbit as compared with wild animals. It is of considerable interest to find that a classification of animals in accordance with their ophthalmological features supports, and is in general agreement with, the best modern classification founded on other characters. Mr. JOHNSON has made a good commencement of what may be termed comparative ophthalmoscopy; the field is large, there are few cultivators, and it may be hoped that he will have time, health, and leisure to pursue it.

## War Office Reform in Relation to the Army Medical Services.

WE would call the attention of all who are interested in War Office reform in general and the new scheme for the reorganisation of the Army Medical Services in particular to the very important Orders which have been issued for the reconstitution of the War Office. It will be remembered that some time ago an independent and influential committee was appointed to go into the whole subject of War Office reform. In due time this committee of business men known as the DAWKINS Committee issued its report and put forward its recommendations, among which was a proposal for the institution of a War Office Board possessing large and far-reaching powers. This proposal has not only been accepted by the authorities in principle, but it has since been extended, amplified, and applied in the directions laid down and embodied in the Orders now issued by the War Office. The new scheme is an elaborate and very important one, and we have now been furnished with a description of the machinery by

which it is proposed to be worked. There is, first of all, to be a powerfully constituted War Office Council, presided over by the Secretary of State for War, or in his absence the Commander-in-Chief, which will meet weekly to discuss and to deliberate upon all matters referred to it by the Secretary of State or brought before it by individual members of the council. The functions of this council are apparently of an extended character with delegated powers and authority commensurate with its responsibilities. The Director-General of the Army Medical Department is to be a member of this council as far as all medical and sanitary questions are concerned. In connexion with this Council an Executive Committee is to be established at the War Office for the purpose of coördinating the business of the office and of securing combined action on matters affecting more than one department. The functions and duties of this permanent Executive Committee and of its respective members are clearly set forth. The Deputy Director-General of the Army Medical Department, or an officer selected by the Director-General, is to be a member. Provision is also made for the formation and summoning of special Departmental Committees to report upon any special subjects or points. The existing Army Board is to remain as it is as regards its constitution and duties with the important addition that the Director-General of the Army Medical Service is to be a member of it—a reform which we have repeatedly called for in THE LANCET. Henceforth, it appears to us, the Army Medical Service will be amply represented in the highest military places and in a position to put forward its proposals and to initiate discussion thereon, and so to exercise an effective influence in all army medical and sanitary questions as well as in those bearing on the health and comfort of troops. Whether the Advisory Board proposed in the report of Mr. BRODRICK'S Committee on the reconstitution of the Army Medical Services may prove to be unworkable or not, it surely cannot weaken the hands of the Director-General on the War Office Council, seeing that his proposals will come before the latter supported by an independent civil element. We pointed out last week that this report was but a series of recommendations, and we asked our readers to think whether it might not be well before virtually condemning an immature and untried scheme—and thereby threatening to arrest the growth of efforts towards reform—to wait until something further was known about it and about the intentions of Government in regard to it. So far, at any rate, the wisdom of adopting that policy seems to have been justified. The Army Medical Service, as it seems to us, when represented upon, and taking part in the deliberations of, three very important boards at the War Office, can scarcely fail to occupy a more influential and powerful position than has hitherto been the case. Other changes are, no doubt, required in the scheme put forward by Mr. BRODRICK'S Committee for the reconstitution of the Army Medical Services—for example, a correspondent points out in our columns this week that from one point of view an actual decrease in pay is being offered to the officers of the Royal Army Medical Corps under the new recommendations; but that of temperate criticism will be the fairest and best spirit in which to approach the report.

## Annotations.

"No quid nimis."

### QUACKS AND AN AMERICAN NEWSPAPER.

A NEWSPAPER published in the United States, the *Philadelphia Times*, appears to have taken a step which should commend it to all decent citizens in the district in which it circulates. It has published a statement to the effect that it declines to accept any advertisements that savour of quackery or fraud and it has defined its position as follows: "The *Times* has drawn a line that it never allows to be passed. It refuses to insert at any price, though they are repeatedly offered, all advertisements of 'diseases of men,' 'female remedies,' 'guaranteed cures,' and such like indecencies, and of massage, clairvoyance, and other cloaks for vice. It equally refuses advertisements which promise something for nothing, that guarantee big dividends or otherwise lure the reader to questionable investments. And it absolutely rejects all objectionable displays and the huge illustrations in advertisements that are offensive to good taste and common decency." We commend the *Philadelphia Times* for the position which it has taken up and we see no reason why a newspaper that has resolved to keep its columns free from degrading advertisements should not give the fullest information as to its policy to the public for which it caters. In England there are many newspapers which do not publish advertisements of the class first referred to. These are, as a rule, newspapers circulating in classes of the community where such advertisements would not be tolerated or would not secure customers for the advertisers. The majority of newspapers in England which circulate among the lower middle and lower classes of society, and in circles where the credulous and the vicious are likely to form an appreciable element, almost invariably contain advertisements of the more disgraceful kind which the *Philadelphia Times* refuses to accept. It would be utopian for us to hope for the exclusion of quacks' advertisements from newspapers simply on the ground that they contain fraudulent promises of impossible cures and are the means of swindling simple-minded people. It is otherwise, however, when the advertisements deal with the results of sexual immorality and more or less openly proclaim the merits of alleged aphrodisiacs and abortifacients. Recent prosecutions have for a time caused a cessation of advertisements of the latter class; those of the former continue, and it will be remembered that it was the vendors of the female pills and concoctions who were prosecuted—not the newspaper editors who accepted their perfectly candid advertisements. Advertisements relating to venereal diseases and infirmities connected with sexual intercourse are in England declared indecent by Act of Parliament when exhibited near the highway or in public urinals. In newspapers their indecency would presumably be a question of fact for a jury, but the police do not institute proceedings in respect of them. That their suppression is desirable none will deny, for they are not only the product of vice and immorality—they are direct incentives. By a coincidence the *St. Louis Courier of Medicine*, from which we quote the manifesto of the *Philadelphia Times*, contains an abstract of a paper read by Dr. George Engelmann of Boston, Massachusetts, before the Gynecological Section of the American Medical Association last June, in which he gives rather startling figures relating to the apparent increase of sterility among American women and the decrease of fecundity among those married women who are not altogether childless. Primary sterility, together with the condition of childlessness due to miscarriage, he

declares to be, to a large extent, intentional and artificially produced among women in the United States. We need not discuss in detail his figures or his deductions, but we may point out that conditions such as those which Dr. Engelmann declares to exist, and which he naturally deplures, form an appreciable feature in modern social life elsewhere than in America, while they can hardly fail to be largely fostered and developed by the wide circulation of advertisements such as those to which we have called attention, which proclaim and trade upon the sensual aspects of sexual intercourse, encouraging the young and inexperienced to believe that they can indulge and over-indulge their passions with impunity, while those who are suffering from their imprudence are lured by specious promises of impossible or criminal "remedies" and are made easy victims to blackmail and extortion.

#### "IS TYPHOID FEVER INFECTIOUS?"

THIS question arose recently in the Durham County Police-court when an application was made for an order for the compulsory removal to a fever hospital of two young men. It was stated that the house in which the patients lived contained three sleeping-rooms and that 12 people lived in the house. The interest of the case lies in the fact that the chairman of the board of magistrates raised a doubt as to whether or not typhoid fever was infectious and made the following extraordinary remarks: "I remember once having considerable experience in a place where there were 100 cases. We had all the experts of the country there and they declared that it was not infectious." The worthy chairman (he was a canon) must have misunderstood the "experts." We need scarcely say that typhoid fever is not infectious in the same manner that scarlet fever is, but that unless the greatest care is taken with the excreta infection is very easily spread. Fortunately, the practitioner who had seen the cases was present in the court, and having at the request of the chairman "sworn" that typhoid fever was infectious the required order was made.

#### MR. CHAMBERLAIN'S SPEECH ON TEMPERANCE.

THE speech on temperance delivered by Mr. Chamberlain on Oct. 14th at Birmingham was characterised by that practical moderation which he commended to his hearers. Evidently recognising the futility of attempting to deal with any of the controversies which have gathered round this subject he concentrated his attention upon drunkenness as the real object of reforming energy. He noted the obvious impossibility of arriving at national sobriety by any process of legislation however comprehensive. The evidences of improvement observable even without the aid of trustworthy statistics during the last 70 years he attributed mainly to sanitary, educational, social, and religious influences. At the same time he admitted that legislation has its proper place also in the work of reform. He suggested that it should be employed where at present it is not—namely, for the control of licences to grocers, chemists, clubs, and the older beerhouses. He pointed out that if this is not done a diminution in the number of licensed public-houses would prove of little practical value in the interests of temperance. It is encouraging to know, however, that in Mr. Chamberlain's own city of Birmingham this process of gradually thinning out is being systematically carried on by the local magistracy. To what extent it will prove successful in the reduction of drunkenness remains to be seen. Discussions arise from time to time as to how far the presence of temptation in this form is responsible for the excess which has always been associated with it, yet there cannot be any reasonable doubt that self-indulgence in any form owes not a little in the plan of its development to the calls of temptation from without. Surely this is a matter of common experience. It is

probable that a considerable number of persons, especially young persons, become intemperate, not wilfully or suddenly, but gradually by repeated and scarcely noticed concessions to desire. The lack of opportunity alone would in many such cases be enough to restrain this inclination and thus to prevent the formation of a ruinous habit. This, at all events, is the usual rule in regard to other human weaknesses; doubtless it is the rule with alcohol too. For this reason we can quite appreciate the advantage likely to accrue to the public well-being from the proposed reduction in the number of licensed houses, which has grown out of all proportion to the needs of the population. Temperance reformers have always kept this object in view, though they have not always sought to attain it by the wisest methods. In advising them to follow after it with patience, perseverance, and a due regard for common justice Mr. Chamberlain has done good service for the cause they and he, and, we will add, we ourselves also have at heart.

#### THE SANITARY INSTITUTE.

As will be seen in another column, the meeting of the Sanitary Institute this year was productive of many important papers, not the least valuable of which were those contributed by experts on the quality and quantity of water-supplies. Mr. H. W. Russell of the Berkshire County Council contributed two papers, the first of which related to the prevention of pollution within the Thames watershed and the second to the Thames water-supply and storage. He pointed out in the former paper the vastness of the watershed of the Thames. It comprised an area of over 5000 square miles from Banbury in the north to Haslemere in the south, and from Cirencester in the west to Leigh in the east, and in this area no stream or watercourse was allowed to be polluted by the discharge of sewage or other offensive matter under heavy penalties, supervision being managed by a staff of 18 inspectors. He pointed out the importance of securing the coöperation of local authorities. In the latter paper he maintained that the flow of the Thames was abundantly equal to the drinking requirements of the metropolis so long as provision was made for storage. He calculated that there was ample excess to provide storage for 80 or 90 days' supply for London without interfering with the requisite quantity for navigation and for keeping the channel full and flowing. Dr. H. R. Kenwood laid stress upon the importance of making a careful local investigation of all possible contaminating influences of a given source of water-supply. In the discussion that followed Dr. A. Bostock Hill urged the importance of a full analysis being made, drawing attention to the limits of bacteriological examination and deprecating reliance on a negative result. He rightly observed that the expense of analysis was often a difficulty and thus only a partial examination was often made. It cannot be too frequently insisted upon that a periodical systematic examination is better than anything even although a partial analysis is made, for there is the highest significance in the variations of composition and character of a water-supply. Mr. Thomas Caink, engineer to the city of Worcester, presented some interesting particulars in regard to the relation of typhoid fever to the purity of water-supply. He stated that he found that the typhoid fever rates in towns supplied with filtered river water were much lower, generally speaking, than those in the towns supplied from artesian wells and mountains. On Oct. 18th the annual dinner of the Sanitary Institute took place at the Holborn Restaurant when Sir Francis Sharpe Powell, Bart., M.P. Vice-president of the Institute, occupied the chair. He was supported by Sir William H. Broadbent, Sir William Church, and many well-known medical officers of health. In proposing the toast of "The Sanitary Institute and its

President, the Duke of Cambridge," he alluded to the fact that never was there a time when interest in sanitary matters was more keen than now, and the opportunities offered to the members of the Institute were very great. He rejoiced that the Institute was full of energy, and that this energy was being directed to the public welfare. They had made considerable progress and not the least important direction in which it was made was that which resulted in making the people realise the importance of the application of sanitary measures. Mr. A. Winter Blyth, in responding to the toast, said that they were not only a national society but an imperial society in the best sense of the word. He appealed for the support of a scheme for a suitable building for the Parkes Museum of Hygiene. They had raised already by promise about £7000, but at least 10 times that amount was required if they would see a building erected worthy of the museum and of the cause. There were representatives of several municipal authorities present, amongst them being the mayors of West Ham and Dover, who cordially recognised the great assistance in maintaining the public health which their respective corporations received from their medical officers of health and sanitary staff.

#### BAD MEAT.

ON Oct. 18th Thomas Hale of 244, High-street, Shadwell, was summoned at the Thames Police-court for being in possession of a quantity of bad meat which was intended for human food. Mr. G. H. Young, who prosecuted on behalf of the Stepney Council, stated that the defendant traded as a tripe dresser. On July 22nd Mr. Adams (a sanitary inspector) and another sanitary officer inspected the defendant's premises and found in the preparation room a quantity of diseased meat, such as liver, sheep's tongues, brains, and hearts. They also found three pieces of tripe which were bad. In addition were found spleens and ox cheeks which were bad. Good and bad meat was mixed together. In reply to Mr. Newton, who defended, Mr. Adams stated that no bad article was found in the shop. One of his summonses had been dismissed at that court. He did not know that a chief part of the defendant's business was boiling down food for cats' meat. Mr. D. L. Thomas, medical officer of health, stated that the meat found was unfit for human food. Mr. Newton contended that there was no evidence to show that the stuff found was intended for human food. The defendant went into the witness-box and said that it was quite impossible to tell whether tripe was good for human food until it had been boiled. The meat for human food and that for cats' meat were prepared in the same room. Mr. Dickinson said that the defendant would be fined £25 and costs. Mr. Newton thereupon said that his client would appeal, whereupon Mr. Dickinson is reported to have said, "Then I will inflict the full penalty of £50 and £5 5s. costs, and he may appeal on that."

#### MALTA FEVER.

WE have received a copy of a pamphlet on Malta Fever by Dr. J. J. Curry, captain and assistant surgeon, U.S.V., Philippine Medical Service. The article is a reprint from the *Journal of Medical Research*, Volume vi., No. 1. The first portion is occupied with a report of four cases of Malta fever which were observed in the United States Army and Navy General Hospital at Hot Springs. The patients were soldiers and sailors who had returned from tropical stations. Dr. Curry remarks that the four patients were thought on admission to be suffering from chronic rheumatism. They did not improve under treatment, nor did the change to a favourable climate have any beneficial effect. In spite of treatment for rheumatism and malaria more or less regular recurrences of pain, swelling of the joints, and rise of temperature ensued. The conditions lasted a long time—from

six months, the shortest, to 16 months, the longest of the series. The other prominent symptoms were anæmia, profuse sweatings, and constipation. The clinical history of the cases suggested to Dr. Curry the diagnosis of Malta fever, and the result of the serum test corroborated his suspicion. He therefore believes that Malta fever is by no means as limited geographically as heretofore has been thought, and he is convinced that the disease is widespread in tropical and sub-tropical regions. In the second part of the pamphlet he comments on the serum test in Malta fever, and after describing Professor A. E. Wright's method of performing the test he proceeds to give his own technique which is briefly as follows. Tubes, 7.5 centimetres long and from three to four millimetres in diameter, were made from glass tubing and the bottoms drawn out to a long sharp point. These were sterilised and plugged with cotton. Salt solution suspensions were made according to the method used by Professor Wright. The bacteria were killed by heat at 60° C. for 15 minutes, and 0.5 per cent. of carbolic acid was added. As a routine method one drop of blood serum was mixed with 19 drops of normal salt solution, then equal parts of this mixture and the salt suspension of the culture of the micrococcus melitensis were taken and placed in the small tubes with sterile pipette. This equals a dilution of 1 in 40. A reaction was called positive and complete only when, in addition to the precipitation of the bacteria in the bottom of the tube, the supernatant fluid became clear. Normal blood and the blood of those suffering from other complaints, such as dysentery and malaria, may be used as controls. These macroscopical observations may be confirmed by microscopical examinations of drops of the fluid withdrawn by means of a platinum loop. Dr. Curry does not advance this method as superior or even equal to that described by Professor Wright, but refers to it as a process which may be adopted with success.

#### CALMETTE'S ANTIVENENE.

THE following is an extract from a report by the medical officer of the Bengal-Nagpur Railway in India for the month of August:—

"On the night of the 23rd I was called to see a cooly woman who had been bitten by a large snake supposed to be a cobra. She was said to have been bitten at about 7 p.m. and I did not see her till two hours later. She was then practically moribund, the throat paralysed, and consciousness completely lost. All the symptoms of poisoning by colubrine venom were well marked. I injected a full dose of Dr. Calmette's antivenene, but was not sanguine as to the result, the patient's condition being apparently hopeless. The effect of the remedy was marvellous; consciousness returned in 15 minutes, and I was so encouraged by the result of the first injection that I decided to give another dose of the serum. It acted like magic and within three hours of the first injection the patient was well. Dr. Sen, my assistant surgeon, was present at the time. I have sent the notes of the case to Dr. L. Rogers, the professor of pathology to the Calcutta Medical College, and propose to also send a report to Dr. Calmette, who is, I know, always glad to hear of cases in which his remedy has been used. I am satisfied that in even desperate cases we have in Dr. Calmette's serum a really reliable remedy for the bites of poisonous snakes, and I propose to supply all assistant surgeons with a syringe and some bottles of serum. At present only this place and Chakardharpur are so supplied. I am now convinced that the case reported by me in May would in all probability have been saved had a large dose of the serum been injected and had the patient come under treatment earlier."

The value of Calmette's antivenene is generally recognised and many experiments of great interest have been performed with it. The evidence as to the nature of the substance to which its efficacy is due is very striking. When the correct relative quantities of venom and antivenene are mixed in a test-tube and after a short interval are injected into an animal no toxic symptoms follow. If the venom and the antivenene are injected separately into the subcutaneous

tissue toxic symptoms, varying in amount according to the interval between the injections, will appear; if, however, the venom be injected into the subcutaneous tissue and the antivenene into a vein of the animal no toxic symptoms will result. The facts show that the venom is much more readily absorbed than is the antivenene. It is probable that if a person is bitten and the venom is carried directly into a blood-vessel no injection of antivenene would prove of value, though, of course, it should be tried. The active constituents of both venom and antivenene are apparently proteids. Unfortunately, in most cases of snake-bite, the antivenene is not available in time to prove of use.

#### THE VACCINATION LEAGUE.

THE Vaccination League is an opportune movement. This association has been started, we are informed, to spread a wider knowledge of the benefits derived from vaccination and a better understanding among the general public of the advantages arising from preventive medicine and practical sanitation. The League already counts among its supporters a number of influential laymen interested in the subject, and numerous well-known medical men, including Mr. Hutchinson, F.R.S., member of the recent Royal Commission on Vaccination; Sir Alfred Garrod, F.R.S., Physician Extraordinary to Her late Majesty Queen Victoria; and Professor Charles Stewart, F.R.S., of the Royal College of Surgeons of England. The temporary offices of the League are at 110, Strand, London, W.C., where all information can be obtained from the secretary.

#### THE LEECH MEMORIAL FUND.

THE fund which is being raised to found a memorial to the late Dr. D. J. Leech has now reached the sum of £1230. As it is proposed to close the fund very shortly the committee will be glad if intending subscribers will forward their contributions to the secretary, Dr. E. M. Brockbank, 3, St. Peter's-square, Manchester. We are asked to state that a meeting of subscribers will be held next month to hear the committee's report. Due notice will be given of the date of this meeting and we trust to learn that when it is called the committee will have in hand a sum large enough to found a really substantial memorial. For Dr. Leech must be regarded as a foremost figure in Manchester medicine, and the profession generally owes him a large debt of gratitude for valuable work done both in scientific pharmacology and in practical politics.

#### CONJUNCTIVITIS AND RETINITIS FROM EXPOSURE TO THE X RAYS.

INFLAMMATION of the skin from exposure to the x rays is now well known, but cases of injury to other tissues are very rare. In the *New York Medical Journal* of Sept. 21st Dr. J. W. Sherer has published a case in which conjunctivitis and incipient retinitis were apparently produced by repeated exposure to the x rays. A medical practitioner, aged 29 years, who had been daily exposed to these rays for three and a half years, was seen on Oct. 11th. About six months previously his eyes became sensitive to sunlight and the ocular muscles were unduly fatigued by near work. Slight conjunctivitis had just appeared. Vision was normal. The discs were slightly blurred and the fundi were abnormally red. A 1 per cent. solution of nitrate of silver was prescribed for the conjunctivitis, to which it quickly yielded. When the patient was seen again, on Nov. 10th, desquamative dermatitis, accompanied by bronzing, had appeared on the face—a condition characteristic of the action of the x rays. The eyebrows and eyelashes were almost completely lost. The conjunctivitis had recurred, but was limited to the lower lids. The fundi were much more congested and reddened. The discs were much blurred. The eyelids

were then protected by steel plates with plate-glass windows. The conjunctivitis and retinitis disappeared in about a month. Nine months later the fundi were normal and the eyebrows and eyelashes were growing again and there was only a trace of redness in the conjunctiva. It is of interest that of three cases of cancer in the eye treated by the patient with the x rays in which 75 sittings were given irritation of the organ occurred in only one. In a fourth case in which 37 severe applications were made ulceration of the cornea occurred. Dr. King of Toronto has reported a case of conjunctivitis, loss of eyebrows and eyelashes, desquamative dermatitis, and exfoliation of the hair and nails from the x rays.

#### MEDICAL SERVICE AT ST. PAUL'S CATHEDRAL.

THE annual festival service in connexion with the Guild of St. Luke was held at St. Paul's Cathedral on Thursday, Oct. 17th. There was a very large congregation and a good proportion of the seats under the dome was reserved for those members of the medical profession who attended in their academic robes. The musical portions of the service were sung by the special choir of the London Church Choir Association, under the direction of Dr. H. Walford Davies, organist of the Temple Church and honorary conductor to the association. The setting of the Magnificat and of the Nunc Dimittis was Stainer in B flat; the anthem "Lead, kindly Light," was also sung to Stainer's setting, the exquisite rendering of which (as, indeed, the whole service) reflected the greatest credit upon conductor and choir alike. The lessons, which had special reference to the healing art, were read by the Rev. W. H. H. Jervois, Vicar of St. Mary Magdalene, Munster-square, W., and the prayers were intoned by Minor Canon Tapsfield. Canon Gore was the preacher, and in an eloquent sermon, founded upon Eccles. ix. 17, he drew an analogy between the priesthood of theology and the priesthood of medicine, both having to deal largely with ignorance and sin, men frequently looking to the physician to escape the penalty of their misdeeds. He urged his hearers to live up to the responsibilities of their profession, and instanced the life of the late Sir James Paget as one worthy of emulation.

#### INFECTION AFTER DEATH.

WE have received a letter from a correspondent, presumably an American, stating that in his opinion there is a source of danger in the propagation of disease which in this country is entirely overlooked—namely, infection from the bodies of those persons who have died from an infectious disease. To remedy this he suggests that all funeral carriages of whatever class should be lined with wood or some material such as lincrusta, so that the inside of the vehicle could be easily washed. The upholstery fittings should be so arranged that they can be easily removed. Further, he urges that the undertakers' clothes and those of all the attendants should be disinfected and the "men wash with disinfecting soap." He concludes by saying that "this system is not generally adopted in America, but where it has the results have been most satisfactory. The public run great risks in coming in contact with undertakers without this precaution." It would be interesting to know the data on which our correspondent bases his conclusions. We believe that he has immensely exaggerated the dangers which he mentions, and we are not aware that disease has ever been shown to spread in the manner he suggests. We should certainly advise, in the case of death from an infectious disease such as small-pox, that the body be enveloped as speedily as possible in cloths wrung out in some disinfectant solution, and that the coffin should be closed early; these precautions having been taken we do not

agree with our correspondent that "the public" would run great risks in coming into contact with those whose duties necessitate their removing dead bodies. A plan such as we have suggested is particularly important in dwelling-houses where many people are crowded together. Amongst certain classes it is the custom to ask their neighbours to view the body of the deceased; such a custom cannot be too strongly deprecated. In some districts capacious mortuaries have been established for the reception of dead bodies until arrangements are made for their interment and certainly such a course should be made obligatory in those cases in which the body has to be retained in rooms where surviving members of the family have to sleep or to live.

#### SMALL-POX IN LONDON.

DURING Monday, Oct. 21st, 10 fresh cases of small-pox were admitted to the hospitals of the Metropolitan Asylums Board; during Tuesday, Oct. 22nd, there were five fresh cases; and during Wednesday, the 23rd, there were five fresh cases. The Local Government Board have issued a circular to the Metropolitan Boards of Guardians saying that "in view of the outbreak of small-pox in London they think it desirable to draw the attention of the guardians to the circular letters addressed to them by the Board on Feb. 21st, 1893, and July 30th, 1895. Portions of these letters and the remainder of the circular run as follows:—

There is no doubt that there is considerable risk of small-pox being spread by means of casual paupers, and the Board trust that the guardians and their officers will take such measures as will tend, as far as possible, to diminish this danger.

The Board must, at the same time, observe that when a case of small-pox occurs, whether in the casual wards or in the workhouse, and, indeed, in times of small-pox prevalence generally, it is, in the opinion of the Board, of the greatest importance that measures should without delay be taken to secure, as far as practicable, vaccination or re-vaccination of the other inmates, so far as the medical officer may consider needful. Care should especially be taken that the officers and other persons employed in the casual wards or brought into personal contact with a case of small-pox, if they have not within a sufficiently recent period been either successfully re-vaccinated or had small-pox, should at once be re-vaccinated as a protection against the disease.

The Board request that whenever there is an occurrence of small-pox or any other dangerous infectious disease in a workhouse, including any case occurring in the casual wards, a report of the fact may be made to the Board by the medical officer, the report being accompanied by a statement showing for each case the date of attack and source of infection, so far as may be known. This report should be made in addition to the immediate notification of the case to the medical officer of health.

In their letter of July 30th, 1895, the Board further expressed a desire that the medical officer would, in reporting any case of small-pox as requested above, state what provision had been made for preventing the spread of the disease among the inmates and for the isolation and nursing of the patients whilst they remain under his charge. The Board wish that this desire should be complied with, and that in the case of small-pox occurring the medical officer should fully inform the Board of such measures as may be taken with regard to vaccination and re-vaccination.

I am directed to request that the guardians will be good enough to place a copy of this circular in the hands of the medical officer, the master of the workhouse, and the superintendent of the casual wards.

I am, Sirs, your obedient servant.

S. B. PROVIS, Secretary.

This circular is by no means unnecessary. Boards of guardians like the London School Board are popularly elected bodies, and their members go upon the principle of conciliating what they call "the people," meaning thereby not the hard-headed common-sense working-man and ordinary middle classes, but the fools and faddists of every degree. Hence the action of the London School Board in putting every obstacle in the way of public vaccinators exercising "tyranny" and "compulsion," or, in other words, looking at a child to see whether it may or may not be ill. Hence, too, the pigheadedness shown by the Hackney Board of Guardians with reference to the same matter. As to revaccination, it is of little use for the Local Government Board to say that care should be taken that certain persons should at once be revaccinated, when the Government have acted in the regrettable way that they have as regards this very question of revaccination. Lord Harris, on behalf of the Government, practically promised that a Bill dealing

with this subject would be brought in during the session following that in which the Vaccination Bill of 1898 became law. From that day to this the Government have never said a word as regards revaccination.

#### THE ELECTION OF DIRECT REPRESENTATIVES UPON THE GENERAL MEDICAL COUNCIL.

Mr. Victor Horsley, Mr. George Brown, Dr. S. Woodcock, and Mr. George Jackson are announced to speak at a meeting to be held to-day (Saturday) at 3.30 P.M. at Newcastle, Mr. Rutherford Morison in the chair. Dr. J. G. Glover was also invited to address the meeting, but owing to indisposition will be unable to be present.

#### UNIVERSITY COLLEGE MEDICAL SOCIETY.

At the opening meeting of the University College Medical Society held on Oct. 16th at University College, London, the chief event of the evening was an interesting discourse by Mr. Christopher Heath, entitled, "Fifty Years of Medical Life." The presence of many ladies in the audience supplied Mr. Heath with an opportunity which he did not fail to utilise of drawing attention to the great change that had taken place in the medical world concerning the question of the admission of ladies into the profession of medicine. Referring to his experience in America a little while back when he delivered the Lane Lectures in San Francisco Mr. Heath said that the lady students were quite equal to the men in aptitude and attention. He remembered the great controversy as to whether women should be allowed to study medicine at all, and he recalled how Miss Garrett, who was now well known as Mrs. Garrett Anderson, was in great difficulty as to where she could study, and she applied, among other places, to Westminster Hospital, where he was then attached, to ask if she could receive her medical education at that institution. The staff held a solemn meeting, presided over by an old bachelor, and the unanimous opinion arrived at was that they were unable to comply with the request because if they taught ladies they would not be able to teach gentlemen. At the present time the School for Ladies at the Royal Free Hospital was justly recognised as a great success. Mr. Heath concluded his reference to lady doctors by describing how he went over a certain infirmary where one of the medical posts was held by a lady. In answer to his inquiries he was told that she had the entire care of all the female patients, did all the dispensing, and kept all the books. That seemed rather an unfair division of labour and appeared a somewhat unjust way of treating a lady practitioner. Mr. Heath was only 16 years of age when he persuaded his father that he had had enough of school and entered at King's College Hospital. He had to wait, however, till he was 21 years of age before qualifying. In those days there was no entrance examination before becoming a medical student and he recollected how profoundly ignorant some of the men were. At the present day, of course, students had to pass a preliminary examination of a reasonable character, but he was afraid in the hurry and rush of passing the numerous examinations now imposed that men quite forgot that there were such things as British classics. Medical students, he said, did not read Dickens, they did not even know Thackeray, and as for studying Shakespeare, that was out of the question. He thought it was a pity that that kind of culture had entirely gone out of fashion. Nowadays, if a man knew a little Latin, a little mathematics, and had a slight smattering of French and German, he at once became quite a superior person. In regard to learning anatomy there were no sections in his early days such as there were now in every museum in London, and it was rather a struggle in those days to learn anatomy. There was one feature of his student days which Mr. Heath said he regretted had been

altered and that was that the students were then urged to attend the hospital practice every day. Now until a man had passed his anatomy and physiology he was forbidden to go into the wards. Mr. Heath took credit for introducing an improvement in the manner of tying ligatures, for changing the description of the fibula which was formerly described as a three-sided bone, and for showing how to stop hæmorrhage in operations on the tongue. No one, said Mr. Heath, had yet arrived at the end of his instruction; his studentship, he was happy to say, was still going on although he had completed 50 years of medical life.

#### EARL GREY'S PUBLIC-HOUSE TRUST MOVEMENT.

PERHAPS no movement in favour of temperance has evoked a more intelligent interest than that conducted by the Public-house Trust Association. The title does not suggest a revolutionary or a Utopian inspiration, and the plan of operations as described in the first report of the association is deliberate and businesslike. Its great aim is to eliminate private interest from the retail trade in liquor and to place that trade in the hands of limited companies which shall conduct it on temperance principles as a public trust. The return to shareholders is limited to 5 per cent. and all surplus revenue is devoted to objects of local or national benefit other than those chargeable to the rates. Managers are appointed to the public-houses owned by the association and are paid a fixed salary. No profit on intoxicants is allowed to them, but they receive a percentage of profit on the sale of food and non-intoxicants. These public-houses being strictly restaurants are bound to supply non-alcoholic beverages and food as well as beer, wine, or spirits, all of guaranteed quality, and they must be managed with full consideration for order, cleanliness, and the public comfort. Drunkenness will not be permitted and the licensing laws for the regulation of public-houses will be strictly enforced. No attempt will be made to push the sale of alcoholic drinks, but every means will be used to present food and non-intoxicants in such a way as to encourage their consumption. The association proposes to accept all new licences which may be issued and to undertake the control and administration of all public-houses thus established. Many land-owners have also placed licensed premises on their property under the control of the association and it has been found that existing licences can be purchased for its purposes from time to time on favourable terms. As illustrating the share taken by local self-help in such transactions we may mention that a public-house at Cowdenbeath, Fifeshire, has been acquired by the miners and workmen of this district with the help of the association and in conformity with its objects. Already 14 branches of the association have been formed, six in England, six in Scotland, one in Wales, and one in Ireland. The People's Refreshment House Association, moreover, an older and allied organisation, manages 14 licensed houses on similar principles. It is intended that a Public-house Trust Company shall be formed in every county and shall be represented on a central executive council. The progress made so far in this direction is certainly encouraging and we can only regard this fact as one of the surest evidences of an increasingly healthy national opinion on the whole subject of alcohol in relation to temperance. It is significant that several of our colonies have set up a closely similar ideal in dealing with this question. The recently founded South African Alliance which has its headquarters in Johannesburg looks to Government control in one form or another and its substitution for private interest in the retail trade in intoxicants as the only generally applicable means of temperance reform. South Australia goes a step further and would have the trade owned,

regulated, and carried on by the Federal Government. The Natal Legislature has passed a measure enabling any borough to acquire the exclusive right of retailing intoxicating drinks within its limits. The plan suggested by this enactment comes nearer to that of the Public-house Trust Association than either of the others, and we cannot but think that in both cases administrative independence of State control is an advantage alike to the State and the reforming societies. In young communities the importance of this point may not be easily realised, but there comes a time to all growing States when expansion brings with it great extension of political responsibility, and then it is felt that social questions are best entrusted to the hands of municipal or other local councils. Such movements as that of temperance reform should rather be fostered than directed by the State, but they undoubtedly deserve all reasonable encouragement. This we do not doubt will be accorded alike to the efforts of the Public-house Trust Association and of the different colonial alliances.

#### THE AFTERNOON LECTURES AT THE BROMPTON HOSPITAL.

THE lectures to be delivered during the coming winter session at the Brompton Hospital for Consumption and Diseases of the Chest are of particular interest. The opening lecture was delivered on Wednesday last by Dr. Theodore Williams who took as his subject "The Prognosis of the Different Forms of Pulmonary Tuberculosis" and treated it with the thoroughness that might be expected from his long experience. These lectures at the Brompton Hospital are free to all qualified medical practitioners as well as to the students attending the practice of the hospital, but we doubt whether their value is sufficiently recognised by the medical profession. As illustrative of the lectures the most valuable clinical material is shown, and the special points of diagnosis are demonstrated by men who have made exhaustive study of their subject. The treatment of phthisis is a matter of first importance to all medical practitioners, and we cannot help being surprised that the opportunities for learning new things and for refreshing acquaintance with old things that are offered by the lectures at the Brompton Hospital are not more freely taken advantage of. Very large audiences could hardly be expected, because the medical profession is a busy one, but we certainly think that the lectures at Brompton might receive more support than they do.

#### PAUPER CHILDREN AND CLEANLINESS.

ACCORDING to the *Daily Telegraph* the gentleman charged with the periodical inspection of Hendon Workhouse has made certain suggestions to the board of guardians as the result of a recent visit to which the board, through its chairman, has pledged itself to give careful consideration—suggestions which are worthy of the consideration of similar bodies throughout the country. He recommends among other things that each child in the workhouse should be supplied with a separate towel, toothbrush, hairbrush, and comb, and that they should all be provided with night-dresses. He also advises that a dentist should be engaged to examine and attend to the children's teeth once in every quarter. The shock of such innovations, had they been made on behalf of *Oliver Twist*, would have brought Mr. Bumble's career to a premature close to the disappointment of novel-readers, but they are really sanitary precautions rather than the pampering of pauper children, many of whom will probably regard them as irksome additions to the discipline which rules their lives. The common use of towels, hair-brushes, and combs must obviously promote the spread of those epidemics which are not easy to prevent altogether.

where children are congregated, while the need for use of the toothbrush and the visit of the dentist are equally real. It is well known that unsound teeth constitute one of the principal causes of the rejection of recruits for the army and navy, while the necessity for the precautions taken on enlistment has been emphasised by the requests for pocket mincing machines for our soldiers and sailors engaged in the South African campaign. Soldiers and sailors are of course not the only section of the community to whom inability to masticate hard foods causes inconvenience and ill-health in after life, which inability can when young would minimise or prevent.

#### LONDON FOGS.

In the report of THE LANCET Special Analytical Sanitary Commission on Smoke Prevention and Perfect Combustion which was published in THE LANCET of Nov. 25th, 1898, p. 1326, appears the following sentence: "If this enormous increase [of gas] can be successfully grappled with at a single day's notice and maintained for several days (it is often only a few hours' notice for there are no means of ascertaining the precise moment when fog appears or when the temperature will suddenly fall), it is evident that even the existing plant, both manufacturing and distributing, is equal to the increasing requirements necessitated by the application of gas for purposes other than those of lighting." Those remarks were made in connexion with the proposal to substitute gas for coal for domestic heating purposes. The report referred to related to an inquiry undertaken to show that the introduction of gas as a general heating agent was not only practicable, but that if a system of gas-heating could be universally adopted one of the worst factors concerned in the production of smoke and fog in the metropolis would be overcome. In other words, the inquiry was undertaken in the interests of public health. Since the publication of this report it just happens that the severity and frequency of London fogs have steadily diminished according to the meteorological authorities who are inclined to attribute this fact to the increasing use of gas for heating purposes. Apparently the public health aspect of the matter has never appealed to our public authorities sufficiently to arouse them into an active state of inquiry directed to the suppression of the smoke evil, but an inquiry is now promised which has been prompted, oddly enough, by the representations of electric and gas-lighting companies. It might be thought that it was congenial to the interests of the directors and shareholders of public lighting companies that fog should remain. The demand for artificial light is greater than ever, chiefly on account of the enormous expansion of the inhabited areas in and around the metropolis. The supplying companies can cope readily enough with this demand in normal times, but on the advent of sudden darkness, as by fog, of which they have no means of obtaining warning, their resources, as many of our readers to their discomfort and inconvenience know too well, are strained to the utmost. And this fact has led the companies concerned to appeal to the Meteorological Office for a system by which special forecasts or warnings of the approach of fogs could be issued to them. There are doubtless a good many people in addition to electric supply and gas companies who would gain by being put in touch with warnings of this kind. It matters little by what channel an end is obtained or who attains it so long as the result is good and of service to the country. We had hoped that the question of London fogs would have been seriously approached from the public health standpoint, but that it is going to be approached from the standpoint of expediency does not after all matter, for the inquiry is calculated to add to our knowledge of fogs and their formation, and recommendations will surely suggest themselves as the outcome

of the inquiry as to the steps that might be taken to minimise the evil. We recognise the good work being done by the Coal Smoke Abatement Society, a work that is only imperfect for the want of funds. The Meteorological Office have communicated with the London County Council, and the General Purposes Committee have practically agreed to coöperate with the meteorological authorities. The subject of inquiry will be the occurrence and distribution of fogs in the London district and their relation to other atmospheric and local conditions. It is now proposed: "(1) That a gentleman of suitable scientific qualifications be engaged by the Meteorological Council for a limited period to formulate instructions and a scheme of observations and to conduct the investigation; (2) that the observations be taken at the various fire brigade stations and by men of the Fire Brigade, and also if it can be so arranged at other institutions of the London County Council; (3) that the returns be sent from the various stations and from any other institutions selected directly to the Meteorological Office; (4) that the Meteorological Council do arrange with the police authorities for observations to be taken at selected positions outside the County of London; (5) that all responsibility as to the conduct of the investigation and any published results of such investigation do rest with the Meteorological Council; (6) that a copy of the complete returns and 12 copies of a report thereon by the Meteorological Council be supplied to the London County Council; and that the London County Council do contribute a sum of £250 for the investigation." It is reported that these proposals, which were accepted by the London County Council at its weekly meeting held on Oct. 23rd, represent a satisfactory and practical arrangement and that the Fire Brigade Committee will raise no objection, and that the chief officer of the Fire Brigade is prepared to conduct the work also as far as the brigade is concerned, provided that the instruments intended to be used for the observations are the ordinary hygrometric instruments, such as are used in the Royal Navy. We should like to add one other recommendation and that is, that the officers of the Coal Smoke Abatement Society, presided over by Sir William Richmond, should be asked to give their assistance in this matter. We are sure that they would be perfectly willing to do so, and they are in possession of interesting and valuable statistics germane to the inquiry. The results will be looked forward to with interest and everybody will wish the inquiry to be brought to a successful issue, so that our electric lighting and gas companies need not be worried to meet the demands for extra light necessitated by the onset of fog, and that some means will be found by which the formation of black stifling fogs may be to some extent prevented. Mists are inevitable in this climate in the winter, but it should be an offence everywhere to blacken them with smoke. Artificial light is a necessity, but it is as nothing compared with the necessity of pure air and an undarkened day.

#### STATE CHILDREN IN AUSTRALASIA.

A PAPER read before the State Children's Association by Miss Hilda Martindale gives an interesting account of the methods of dealing with orphan and neglected children in South Australia under the State Children's Act of 1895. A council consisting of six ladies and six gentlemen has been appointed with power, subject to the approval of the Governor, to provide and to supervise institutions for the care of State children, to board out and to grant licences, and to control lying-in homes, funds being voted by Parliament. The children thus provided for are those destitute, neglected, or convicted. Any constable may without a warrant bring any child who appears destitute or neglected before the justices, who may then order him

to be sent to the receiving depôt at Adelaide, where several cottages are provided for the purpose. A room is set apart at the office of the council where the magistrate attends to deal with neglected children and juvenile offenders, the parents being summoned to be present. Thus the children do not come in contact with the police-courts or with paupers. The justices can order a child to be detained at an institution till the age of 18 years. In June, 1900, the department had control of 1248 children, of whom 1016 were either boarded out, placed at service, or adopted; 57 in the receiving depôt; 12 in hospitals or in asylums for the blind or imbecile; and 125 in reformatory homes. One of the most important differences between the legal provision for destitute children in South Australia and that in England appears to be the difficulty which is met with by the Poor-law guardians among us in dealing with the "ins and outs," or children removed from schools by pauper parents for their own purposes—a practice which frequently cancels any effort in training to habits of industry and thrift. The provision of receiving depôts for children apart from the workhouse, and special magisterial courts for dealing with juvenile cases, and the power of detention up to the age of 18 years in the case of children of unworthy parents, suggest reforms that might well be introduced into this country by the Local Government Board. We think, however, that the methods of the Australian courts should be improved by the requirement of a medical examination in every case before commitment; the fact that 1 per cent. of the children received are placed in hospital or asylums shows that "defective children" are as frequent in Australasia as among our own population.

#### THE DIRECTOR-GENERAL AND THE DEPUTY DIRECTOR-GENERAL OF THE ARMY MEDICAL SERVICE.

THE King has approved of the appointment of Surgeon-General W. Taylor, C.B., to be Director-General of the Army Medical Service, and on the retirement on Dec. 31st of Surgeon-General H. S. Muir, C.B., Lieutenant-Colonel A. Keogh, C.B., will take over the duties of Deputy Director-General, with the temporary rank of Surgeon-General. Surgeon-General W. Taylor, C.B., joined the Army Medical Staff in 1864 as assistant-surgeon; he became surgeon in 1873, surgeon-major in 1876, brigade-surgeon in 1890, surgeon-colonel in 1895, and surgeon-major-general in 1896. He served with the Jowaki Afridi expedition in 1877, receiving the medal, and with the Burmese expedition in 1885-86 on the staff of the Commander-in-Chief in India, for which he was mentioned in despatches and received the clasp. During the Japan and China war in 1894 he was attached to the headquarters of the Japanese army and received the Japanese war medal. He served with the expedition to Ashanti under Sir Francis Scott in 1895 as principal medical officer with the force, and for his services on that occasion he was promoted to surgeon-general and was granted the Queen's Star. In the Soudan campaign under Sir H. (now Lord) Kitchener, in 1898, he also served as principal medical officer and was present at the battle of Khartoum. He was mentioned in despatches and received the distinctions of C.B., of the Medjidie (second class), as well as the British medal, and Khedive's medal and clasp. Lieutenant-Colonel A. Keogh was a member of Mr. Brodrick's Committee which was appointed to consider the reorganisation of the Army Medical Services. He entered the service in 1880 and reached the rank of lieutenant-colonel in 1892 and brigade-surgeon-lieutenant-colonel in 1900. He served in South Africa with the rank of colonel, and for his services there was made a Companion of the Order of the Bath. We congratulate these gentlemen on their appointments and the department upon having secured good men to do the

arduous work that lies before it. Nor would we lose the opportunity of saying a few words of adieu to the late Director-General, Surgeon-General J. Jameson, C.B., and the retiring Deputy Director-General, Surgeon-General H. Skey Muir, C.B. Upon Surgeon-General Jameson, who was throughout ably assisted by Surgeon-General Muir, was thrown all the responsibility of preparing the medical arrangements for the South African war, and, as far as the methods of the War Office and the exigencies of actual campaigning allowed, his enormous labours were successful. He has so far gone unthanked, but he may be certain that his professional colleagues know the value of his work and will not allow the public to forget it.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope, received at the Colonial Office on Oct. 17th, states that for the week ending Oct. 12th there were no cases of plague in the Cape Peninsula. At Port Elizabeth the cases were: coloured persons, 1; Chinese, 1; natives, 1. The deaths from plague were as follows: Cape Peninsula, 0; Port Elizabeth, 1 (a European). The area of infection remains unchanged. There were no cases of plague in persons under naval or military control. As regards the Mauritius a telegram from the Governor, received at the Colonial Office on Oct. 18th, states that for the week ending Oct. 17th there were 57 cases of plague and 36 deaths.

#### DISCRIMINATION IN CHARITY.

DR. T. D. ACLAND is to be congratulated on the prompt and efficient steps which he took to discover the circumstances in which Mr. William Dyer Frazer, an old pupil of his, believed by him to be in South Africa, appeared to be soliciting alms from an address at Brighton. As a sequel to Dr. Acland's investigations, one Robert Wilson was speedily haled to the police-court, charged with personating Mr. Frazer, and was committed for trial. The trial took place at the Old Bailey on Tuesday last, and Robert Wilson, ex-postman, was sentenced to three years' well-deserved penal servitude. We congratulate the Medical Defence Union, who undertook the prosecution, on the result. The prisoner was shown in the evidence to have obtained several sums of money from medical men by like fraudulent methods, and was certainly unfortunate in the selection of the last intended victim to whom he addressed himself, for in addition to the personal acquaintance and interest taken in Mr. Frazer by Dr. Acland, Sir William Mac Cormac was able to show a letter which he had received to a brother-in-law of the supposed mendicant, Mr. H. C. Crouch of 55a, Welbeck-street, London, W.; but in any case the course he was pursuing was bound in the long run to lead to detection. Medical men are so frequently the victims of impostors that it may not be out of place to point out to them the possibility as well as the wisdom of making inquiries where persons claiming to be members of their profession make this a reason for demanding their sympathy and assistance. The career of the future medical practitioner is one with which many are necessarily acquainted long before his name appears upon the Medical Register, and every stage of it is recorded, while from the date of his registration as long as he continues to practise his life is lived more or less in contact with his professional brethren and before the eyes of the public. Inquiry is therefore almost always possible, and although prompt attention to the request made may at first seem the only way to relieve pressing need the truest kindness may be that of him who takes the trouble to learn all the facts which have given rise to the appeal before him. To relieve effectively where real need exists is to exercise charity; to give indiscriminately without taking further trouble in the matter is at

best to apply a palliative that is no remedy, while at the worst it rewards imposture.

#### VACCINATION PROSECUTIONS IN LEICESTER.

ON Wednesday last the Leicester borough bench dealt with proceedings instituted by the vaccination officer of Leicester against Mr. Herbert Moore, the parent of an unvaccinated child, under Section 29 of the Vaccination Act of 1867. In defence an elaborate argument was set up, which rested mainly upon two contentions, the first that the vaccination officer should have received the instructions of the board of guardians before taking action, and the second that it is essential to the case for the prosecution under this section that the fact of the public vaccinator having visited the home of the child and having offered to vaccinate should be proved. The justices by a majority decided in favour of the prosecution and imposed a penalty, whereupon the defendant's counsel asked that a case should be stated for the opinion of the High Court. This application was acceded to by the bench, and the result of the appeal will be watched with interest. The practice of raising technical objections such as these before magistrates has become extremely common, and in some places has reached such a pitch that, however straightforward the facts of his case may be, the vaccination officer is obliged to appear by counsel or solicitor, with the result that the ratepayers are saddled with much unnecessary expense, while quite a number of witnesses, professional and other, who can ill spare the time, are constantly compelled to be in attendance. The sooner, therefore, that these questions are authoritatively decided by the courts and the proper procedure determined by binding authority the better for all concerned. Meanwhile, we trust that the Local Government Board will not relax its efforts to obtain compliance with the law in Leicester. Recent letters to local papers, we observe, protest loudly against "tyranny," "coercion" and the like, but it is hard to understand what tyranny can be involved in requiring obedience to the existing vaccination law when certificates of exemption can be had at Leicester practically for the asking. Anti-vaccination leaders in Leicester at present work hard to dissuade parents from taking out these certificates—a fact which suggests that they themselves realise the increase in vaccination that is likely to result as soon as the citizens come to understand that they cannot escape from the legal obligations which the Vaccination Acts still impose upon them.

#### SMALL-POX AMONG HOP-PICKERS.

IN a report on an outbreak of small-pox within the borough of Finsbury, Dr. George Newman, medical officer of health, states that 10 cases occurring at the end of September were attributable to infection derived from 'some hop-pickers' huts on a farm at Northlands, Bodiam, Sussex. We have already referred to the incident in our issue of Oct. 5th, p. 924, but Dr. Newman's report gives further details as follows. A girl from Finsbury who arrived at this farm on Sept. 1st was taken ill on Sept. 10th; spots appeared on her face on Sept. 13th, and on the 15th she returned to London, where she was seen on the 16th and 17th by a medical man who was reported to have said that she was suffering from chicken-pox. She lived in Thomas-street and on Sept. 18th a woman in the same house was notified as suffering from small-pox. Dr. Newman infers that both the woman and the girl contracted small-pox at the end of August. On Sept. 23rd and 24th three children of a hop-picker fell ill on the farm at Northlands, and on being brought to London they were found to be suffering from small-pox. On visiting the home of these people in Vineyard-walk on the 26th Dr. Newman was told that there were several similar cases at the farm, and that all

the hop-pickers in that district were returning to London that night. The South-Eastern Railway Company having been communicated with afforded facilities for examining all the hop-pickers arriving during the afternoon and evening at Charing-cross, Waterloo, Cannon-street, London Bridge, and New Cross railway-stations. Hundreds of these passengers were examined by a party consisting of Mr. Shirley F. Murphy, Dr. W. H. Hamer, Mr. Spon, Mr. Gabb, Mr. Evan Jones, and Dr. Newman. At Cannon-street station at a late hour Mr. Evan Jones was successful in waylaying five-cases of small-pox, all belonging to Finsbury, and these patients were immediately removed to the hospital ships.

#### "PAPER AS A WRAPPER."

OUR attention has been drawn to an article in the *British Baker* on "How Small-pox and Other Diseases are Spread," in which the writer very properly condemns the practice of wrapping up articles of food such as loaves of bread in any sort of paper without reference to its previous history. It is stated in particular that shavings taken from a biscuit tin have been recognised as having been cut from bookbinders' parings and other secondhand paper that has been handled and exposed to contamination. "Waste paper finds its way to paper and rag stores where it may have all manner of abominations in close proximity; it is then picked out, cut into shavings, and we next see it placed on the top of biscuits to fill up the tins." We heartily agree with the *British Baker* that this highly objectionable process should be stamped out by the employment of clean and specially treated shavings. It may be noted that we ourselves pointed out in THE LANCET of June 22nd, 1901, p. 775, in an article entitled "Paper as a Wrapper," that very little discrimination, as a rule, was exercised as to the quality or kind of paper used for the purpose of wrapping articles of food. Although we were able to show that the newspapers of London so frequently used for wrapping up articles of food were free from irritants or poisonous mineral substances or dyes, yet we wrote that "the ubiquitous organism is bound to be present and not unlikely it may be a pathogenic one considering the dirty environment under which waste newspaper is frequently to be seen." We are glad to note that others are taking up this important question.

MR. MALCOLM MORRIS, the secretary-general of the British Congress on Tuberculosis, was entertained at the Café Royal recently by the secretaries of committees and sections, under the chairmanship of Mr. Cutler, honorary secretary of the architectural museum. Fourteen out of 19 secretaries were present, and the opportunity was taken to present Mr. Morris with a dining-room chiming clock as a memento of his labours.

THE Lettsomian Lectures of the Medical Society of London will be delivered by Mr. A. Pearce Gould on Feb. 17th and March 3rd and 17th, 1902, at 9 P.M., the subject being, "Certain Diseases of the Blood-vessels." The annual oration will be delivered on May 26th, 1902, by Dr. Stephen Mackenzie.

WE understand that Sir Joseph Dimsdale, M.P., the Lord Mayor Elect, will preside at a meeting to be held at the Mansion House in January to aid the appeal of Guy's Hospital for a renewal of public support. A sum of £180,000 is required to meet the cost of renovation and extension.

THE KING has commanded that in future the Dental Hospital of London shall be known as the Royal Dental Hospital of London. The new hospital is now finished and in full working order and funds to reduce the debt on the

building fund are earnestly solicited and may be sent to the secretary.

THE annual distribution of prizes at St. George's Hospital Medical School will be made in the board-room of the hospital by the Right Honourable the Lord Chief Justice of England on the afternoon of Monday next, Oct. 28th.

## WATER-SUPPLIES AND RIVER POLLUTION.

A CONFERENCE on Water-supplies and River Pollution organised by the Sanitary Institute was held on Oct. 16th and 17th at St. Andrew's Hall, Newman-street, London, W. The Conference was numerously attended by representatives of sanitary authorities from all parts of the kingdom. Under the chairmanship of Professor H. ROBINSON the Conference discussed on Oct. 16th the Sources of Supply and Watershed Areas, Storage, and Town and Village Supplies. The first three papers on the programme were taken together for discussion.

The first paper was by Mr. J. PARRY, M.I.C.E., on the Protection of Watersheds. The author's conclusions were that if water-supplies were to be protected against the risks of all pollutions prejudicial to health which modern science had revealed the sources of supply, including the entire area over which rain was collected, must be owned by the authority responsible for the waterworks and be managed solely in the interests of the water-consumers. These drainage areas need not be left barren; they could be used for sheep-farming, plantations, and deer parks which would give some return for the money spent in purchasing the drainage area and would satisfy every reasonable demand in regard to the purity of the water-supply.

Dr. E. C. SEATON (medical officer of health of Surrey) contributed a paper on the Protection of Underground Sources of Public Water-supply. He divided the subject into protection against waste and protection against local contamination. He detailed what the Surrey County Council had done in preventing attempted encroachments on local resources for the purpose of insuring a water-supply for London and in adjusting the various needs of the different localities in the county. On the subject of contamination the Maidstone and Worthing experiences aroused uneasiness concerning the safety of certain underground sources of supply. The term "nuisance dangerous or injurious to the public health" should be extended in its application.

Mr. CLAYTON BEADLE communicated the third paper, entitled, The Rights of Underground Pumping in Relation to Flow of Neighbouring Streams. His paper consisted of observations by Mr. Beadle on the depletion for the last 20 years of the river Cray in Kent by the pumping stations at Orpington and Crayford.

Professor ROBINSON, in opening the discussion, said that the causes of pollution could be obviated in a more or less degree. Artificial waste of water should be stopped and natural waste should be utilised.

Mr. R. H. WYRILL (Swansea) considered that better supervision of the catchment area was necessary.

Mr. J. E. BUSH (Melksham) urged that representative authorities should control the water-supply areas. The water-distribution should be in the hands of the county council and pumping-stations for purposes of private and commercial profit should not be allowed.

Mr. W. J. BURGESS (Liverpool Water Committee) said that in many towns the purity of the water-supply was not paid sufficient attention to. It was rarely or never possible to adequately prevent the contamination of wells near sewers and rivers were not much better. The condition of the London water-supply was a danger to the inhabitants of the metropolis and afforded a bad example to other places. Water-supplies should be under the control of public bodies.

Mr. CASTLE (Garfield, Yorkshire) described how the sinking of a pit was a source of waste of water by draining almost every well in the district.

Mr. J. SIDDALLS (Tiverton), who represented a rural district, explained that there should be some new authority to adjust the divergent interests between the large urban and the rural districts. Local wants should be supplied before those outside the district were afforded opportunities of securing water.

Mr. J. FREER (Leicestershire County Council) agreed that the inhabitants of any particular catchment area had a prior right to the local water-supply. What was required was some authorised body who could deal with the watershed areas.

Mr. T. R. SMITH gave some facts concerning the control by the local authority of Kettering over their water area.

Mr. F. VERNEY (London County Council) said that the catchment area for the metropolitan water-supply was becoming more and more tainted every year through the increase of population and high farming. The supply of water for London should be obtained from some source not nearer than the mountains of Wales where absolute purity could be relied upon. London water was well filtered but the public health should not depend upon that.

Several speakers from the body of the hall protested against attacks on the purity of the London water-supply.

Mr. LYONS WALCOTT (Middlesex County Council) urged that districts near large towns required protection for their water-supply.

The next paper was on Rainfall and Population of England and Wales in Relation to Water-Supply, by Dr. H. R. MILL. Dr. Mill concluded that there was rain enough to satisfy the demands likely to be made for water. He did not think that the possibility of failure in supply was at all in question. The cost, however, would be serious and might be prohibitive. Economy was therefore necessary and waste of the water-supply should be carefully guarded against. It was the abuse and not the use of the water that caused anxiety. No district should be able to claim for its own all the rain-water that fell in it.

Mr. W. HODGSON (Cheshire County Council) said that the county councils were not using all the powers they already possessed and therefore further legislation should not be demanded.

Dr. A. GREENWOOD contributed a paper on the Desirability for Reports on the Water-supply of each County. He pointed out that it might be necessary in consequence of increased population to supply one district with water from another district, hence the importance of a full knowledge of the available supply in the various districts.

Dr. W. WILLIAMS (medical officer of health of Glamorganshire) communicated a paper on the Rivers of Glamorganshire, with Remarks on the Rivers of Adjacent Counties. He considered that in Glamorganshire greater progress would have been made in the purification of the rivers if the Local Government Board had not insisted under all circumstances on the hard-and-fast rule of land treatment in addition to artificial filtration. It was also important to have as many joint sewerage districts as possible. No crude sewage should be discharged into the sea or into tidal rivers and estuaries unless careful experiments were made with different floating materials to determine the directions of the currents at various conditions of the tide. Health laboratories should be established for the examination of effluents, of refuse, and of materials discharged into rivers, and these should be under the control of the county councils.

The next paper for discussion was by Dr. J. C. THRESH (medical officer of health of Essex) on Water-supply to Isolated Cottages and Small Groups of Cottages. His opinion was that power should be given for the sinking of a well in a central position and the cost should be charged on all owners within a certain radius whose tenants had not a wholesome supply. Every aggregation of houses should have within a reasonable distance an available supply of wholesome water. Public water-supplies, such as springs in roadside ditches, could be, and should be, protected from contamination and utilised.

The last paper was by Miss COCHRANE on Village Water-supplies. The village water-supplies could be placed in the hands of the county councils and the working expenses spread over the whole county or the owners might be made responsible. Miss Cochrane's opinion as regards the schools was that the Education Department should refuse to pay any grants to those schools which were unprovided with wholesome water.

Considerable differences of opinion were manifested as to the form and wording of several motions submitted to the Conference and finally three motions were passed, the first of which recorded that the opinion of the Conference was that the purity of the water-supply could only be effectively secured by placing such supplies in the hands of representative bodies responsible to the consumers. The second motion was to the effect that county councils should have large powers of control over the question of water-supply.

in their respective county areas. The third resolution urged county councils to investigate the existing condition of the water-supply within their districts.

On Oct. 17th, under the chairmanship of Mr. W. WHITAKER (Croydon), the meeting discussed the subjects of Water Filtration, Purification, and Sterilisation; Distribution Appliances, such as Filters, Taps, Cisterns, &c.; and Prevention of River Pollution.

A paper on Water Supply and River Pollution was contributed by Professor ROBINSON. He said that something had been done towards preventing the pollution of rivers where special Parliamentary powers had been given to public authorities. A certain amount of elasticity should be observed in regard to the rules concerning the condition of effluents and the application of a rigid standard of purity under totally different circumstances should be avoided. The evidence brought before public authorities and commissioners during the last few years pointed conclusively to the certainty that in the near future the waters which had been considered as unfit to be admitted into storage reservoirs would be so admitted instead of being allowed to run to waste. He regarded the utilisation of bacteria in anaerobic or aerobic chambers as the solution of many existing troubles. The preliminary breaking up of organic matter by anaerobes enabled the resultant liquid to be utilised on the land for agricultural purposes with greater advantage than where the sewage was applied in its crude state, and where sufficient land was not available the further treatment of the liquid in suitable beds would enable any necessary standard of the effluent to be reached.

Mr. A. G. LEIGH followed with a paper on the Control of Weirs and Dams on Streams in Relation to River Pollution. He thought that a staff of river scavengers under the direction of the rivers authority was required. These men, divided into parties with districts assigned to each, ought to commence at the source of a stream and work downwards, removing all unnatural obstructions and abandoned weirs and dams, levelling the bed as far as possible, and flushing and cleansing out the sluices behind the dams, and in this manner traversing its whole course. The sanitary conditions of streams would be improved and what had taken many years to form would be removed in as many weeks. Organic matter would be carried away before decomposition had set in and the stream would have an unimpeded flow and would carry its burdens with it. Streams passing through thickly populated towns should have their beds paved to prevent the collection of dangerous matter.

Two papers were communicated by Mr. H. W. RUSSELL (Berkshire County Council). The first was entitled Prevention of Pollution within the Thames Watershed. His experience of the working of the Thames Conservancy Act of 1894 had led him to the general conclusion that when intrusting an authority with powers to prevent river pollution such authority should undoubtedly have control over the whole watershed, not only over the main river, but also over all its tributaries. Local sanitary authorities might be so constituted that though imbued with the best intentions they might find it almost impossible to bring pressure to bear upon local manufacturers, possibly large ratepayers and possessing great influence with their local representatives. It was also advisable that there should be no distinction between the powers relating to the main stream and its tributaries. What constituted an offence in the one case should apply equally to the other. Small communities when called upon to divert pollution from streams often experienced much difficulty in deciding what measures to adopt to meet the requirements. They were frequently without any information as to the methods of treating sewage, and had not the means at their disposal of obtaining expert advice. The small communities frequently applied to the Thames Conservators for suggestions and advice on the subject, but it was not possible for them to undertake that responsibility. A branch of one of the Government departments should collect information for these small communities. He acknowledged the work done by the London County Council by means of their sludge-boats in entirely altering the state of the river in the lower reaches below the metropolitan drainage outfall. In consequence of this improvement an attempt was now being made which would have been hopeless a few years ago, but now promised a reasonable prospect of success, to re-introduce salmon into the river Thames, and no more practical proof could be given of the beneficent result attending the labours of the last few years.

The second paper by Mr. RUSSELL was on Thames Water-supply and Storage. The conditions of the flow of the water had greatly altered in the course of the latter half of the last century. The same causes which produced floods also produced droughts. All over the Thames watershed drain-pipes had been laid down in millions during the time mentioned and the result was that the rain-water was rushed into the river with great rapidity. The consequence was that the water no longer lay upon the ground for a sufficient time to enable any considerable portion of it to reach the springs, and more or less disastrous floods were caused, because the channel of the river was quite inadequate for the sudden strain. In order to get the water away as quickly as possible pressure of the severest nature was put on the Thames Conservancy. Larger weirs were constantly being made and an enormous mass of water flowed down to the sea every year, the want of which they were quite aware would be felt a few months later. At the present time, after comparatively moderate rainfalls, the rise of the river was much more sudden and acute than formerly. A large amount of water could be taken from the river with advantage instead of being allowed to run to waste. The flow of the Thames was such that no one could doubt the capability of the river to spare the enormous volume of water necessary for the metropolitan water-supply. Judged by the statistics of the average flow at Teddington Weir there was an ample excess, sufficient to provide storage for 80 days' supply for the metropolis without interfering with the amount of water required for the purposes of navigation and for the efficient scouring of the channel of the river. Referring to the quantity of water estimated to be required in 1941 he was of opinion that there was an ample excess at times which could be extracted with advantage to the river. In considering the question from the view of London water-supply it must not be forgotten that the reservoirs in the Lee valley constructed or in course of construction had a capacity of nearly 8,000,000,000 gallons. The present average daily withdrawal of water from the Thames by the water companies amounted to about 10 per cent. of the average flow of the river.

Mr. W. G. BAGNALL (Staffordshire County Council) complained of the want of assistance from the Local Government Board. The question of pollution was the only one which the Staffordshire County Council had serious difficulty about.

Dr. G. REID (Medical Officer of Health of Staffordshire) said all that was considered necessary for the purification of an effluent was that it should be sufficiently pure to sustain fish life, but that did not carry with it the removal of bacteria including disease germs. If local authorities had to remove bacteria from their effluents it was a very serious matter.

Mr. TOMLINSON (Northampton) pointed out that the land system of purification was working satisfactorily and that the Northamptonshire County Council was most anxious that the methods of purification should not be made more difficult and expensive.

Dr. S. RIDEAL said that sewage-disposal works should not be looked to for producing drinking water but should be required to give an effluent satisfactory for the river as a river—that is to say, to bring the stream into a condition suitable for fish life. To remove pathogenic organisms was not the function of sewage-disposal works. Water should be purified just before its use by the consumer by municipalities or by the water companies.

Mr. A. BOWES (Lancashire) said that the standards of purity required were too high for the practical cleansing of sewage. It was found that towns of perhaps 15,000 inhabitants could turn out an effluent which satisfied the standard, but where was the town of 150,000 inhabitants which had ever done that? After all these years of legislation they had streams in Lancashire that were nothing but inky black sewers.

Mr. W. D. GIBBINS (Northampton) referred to the sewage farm work of his town, and Lieutenant-Colonel JONES, V.C. (Aldershot), said that what had to be done was to clear out from the rivers any stagnant filth and not to allow it to remain in the river-bed, because the most perfect effluent could be turned out above such a gathering of filth, with the result that the work of purification would have to be done over again. In dry years the mud should be cleared out from the river-bed.

Dr. J. RYLEY (Yarmouth) was of opinion that for drinking purposes it should not be permitted that sewage containing pathogenic germs should flow into a stream leading to a water-supply. To make water companies remove the pathogenic germs in water was not commencing at the right end.

Dr. H. R. KENWOOD (medical officer of health of Stoke Newington and Finchley) submitted a paper entitled A Note with Reference to Water Standards, in which he said that the most an initial analysis of a water could tell was whether the figures of the analysis indicated little or much of organic impurity as judged from certain arbitrary standards. Whether the slight contamination which was practically always discovered was harmful or whether the particular water had recently received slight, but significant and possibly dangerous, pollution, could only be told with certainty by several careful analyses of the same water at short intervals of time and by the careful comparison of the results obtained, or by a comparison between the sample of water and others in the immediate neighbourhood collected from similar sources from the same geological area which were known to be above suspicion. It was a frequent practice, therefore, among those who had to advise as to the wholesomeness of the waters collected for drinking purposes in different districts, to establish local water standards, and a considerable multiplication of these was sometimes necessary even for a small district when the geological formations were much broken up. In his own experience, he had once found it necessary to establish as many as four chlorine standards in one small district. The object of his communication was to draw attention to an interesting and instructive incident which had recently come under his notice and which had destroyed his faith in the value of a chlorine standard in actual practice. The chlorine figure in this instance proved absolutely useless for the purpose of detecting animal pollution. He considered that the chlorine standard figure was useless in the smaller degrees of dangerous pollution and that before giving an opinion as to the safety of drinking a particular water it was of the greatest importance that a careful and open investigation should be made for all possible contaminating influences having regard to the source of the water, and that the circumstances which called for the analysis of a particular sample should always be considered in deciding upon the degree of purity that would justify the acquittal of the water as a possible agency in promoting disease.

Dr. A. BOSTOCK HILL (medical officer of health of Warwickshire) agreed that a full analysis ought to be made in the case of water-supplies. He protested against what was being done by so many authorities at the present time in endeavouring to get an analysis of their water-supply done as cheaply as possible.

Dr. KENWOOD said that a fair price should be paid for a complete analysis of water as it was a long and difficult matter.

The next paper was by Dr. S. RIDEAL on the Purification of Water. He said that the general use of open sand filters for the major portion of the last century had brought about a greater purification in water-supplies than was originally intended, because the primary idea of the open sand filter was simply to remove suspended matter, and it was only within the last 15 years that it had been known that such sand filters in addition improved the bacterial quality. The most important point in judging of the purity of a water-supply at the present time was certainly the typhoid fever death-rate and next to it the general bacterial purity of the water. Turbidity, hardness, and the effect in causing incrustation on boilers were now minor considerations and in a sanitary sense of little value. Sedimentation in storage reservoirs and the different methods of softening, although primarily designed for the removal of suspended solids and mineral matter in solution, also effected a considerable bacterial improvement. Although sedimentation and filtration only indirectly attained bacterial reduction a combination of the two processes could be so arranged as to bring the number of bacteria well below Koch's standard of 100 per cubic centimetre. By using lime as a precipitant in the storage water and a portion of the resulting precipitate as the coagulant to form the artificial *schmutzdecke* in a mechanical filter, a combination of the same effective character was possible. The use of lime as a coagulant in the storage reservoir ensured the absence of plumbo-solvent properties of the water and as the bacterial reduction required was less filtration if resorted to could be augmented and raised. A discussion could be usefully directed towards the question whether purification of public supplies should aim at the whole supply being purified up to the maximum standard of a good drinking water or whether people should be content with a somewhat less purified water for the general supply and sterilise separately in each house such portion as would be

required for food purposes. It is probable that a gallon per head per day of sterilised water would be sufficient for drinking and culinary use, so that only from 2 to 5 per cent. of the total supply would need to be hygienically perfect. The methods for ensuring the absence of pathogenic organisms in the small quantity of water required for drinking purposes could be divided into heat sterilisation, candle filtration, and chemical treatment. He believed that the problem of economical and efficient heat sterilisation was worth the further consideration of water engineers. The Pasteur-Chamberland candle type filter seemed to be the only one destined to survive, and chemical sterilisation could only be regarded as an emergency method. Dr. L. C. Parkes, the author, had quite recently advocated the use of bisulphate of soda as an anti-typhoid, especially for waters containing a large amount of organic matter, and he was glad to hear that that salt was being tried for that purpose on a considerable scale in South Africa. Most investigators, however, favoured the employment of oxidising agents in some form for sterilising waters. Ozone was so easily obtained that in several directions it had been tried even for purifying public supplies on a large scale, and it might in the near future be used extensively as a "finisher" in the purification of water.

Mr. T. CAINK (City Engineer, Worcester) gave the details concerning the drop in the typhoid fever rate at Worcester directly the water-supply had been improved in the year 1894.

Mr. WATSON (Bradford) said that the Bradford Corporation had adopted the method of lime precipitation many years ago.

Mr. W. J. BURGESS (Liverpool) said that they had a bacteriological examination of the water every day in Liverpool.

Dr. BOSTOCK HILL protested against judging of the purity of a water-supply entirely by the typhoid fever death-rate. If they were to do so in many instances they would be doing injustice to a water-supply. In two epidemics of typhoid fever he had found that the water-supply was not in any way at fault.

Dr. S. RIDEAL said that the municipalities should purify the water just before it reached the consumer.

Mr. F. VERNEY (London County Council) read a paper on the Value of Soft Water, and in the discussion which followed Mr. MATTHEWS (Southampton) and Mr. CLAYTON BEADLE joined.

The proceedings terminated with a vote of thanks to the Chairman, proposed by Sir F. S. POWELL, M.P.

## LONDON SCHOOL OF TROPICAL MEDICINE.

AN influential meeting was called together by the Seamen's Hospital Society on the occasion of the opening of the third winter session of the London School of Tropical Medicine to hear Lord Brassey deliver the opening address at the Royal United Service Institution, London, on Oct. 16th.

Lord BRASSEY explained that the meeting was for the purpose of obtaining further funds to enable the Seamen's Hospital Society to carry on its work in the treatment of tropical disease. The Colonial Office and Foreign Office in 1899 had contributed £3500 to the school and the India Office had subscribed £1000. The judgment, therefore, of those Government departments was in the highest degree favourable. The school was originally intended for the instruction of surgeons in the colonial and Indian services, but private students, missionaries, medical men, and others had been admitted. Experience had shown that the demand for instruction in tropical medicine was much greater than had been originally anticipated. During the last session it had been found necessary to refuse several students, and some four or five had been compelled to postpone their attendance until the next session. To carry on the work efficiently further funds were required to enlarge the school and to place it on a sound financial basis. The importance of the health of Europeans in the tropics could not be over-estimated, especially to a country like ours that depended for colonial prosperity upon the efficiency of our fellow-countrymen in tropical countries. A healthy community gave continuity of

administration to the Government; diminished sick leave through improved conditions of health, and conducted enormously to efficiency of administration. In commercial operations it was all important that those who conducted them should not be too often away on account of sickness. Sir Francis Lovell was about to proceed to the tropics on behalf of the Seamen's Hospital Society to make known the advantages of the London School of Tropical Medicine, and to endeavour to raise funds on its behalf. The school needed a sum of £100,000, but large as that sum was it was yet a small one for the great British Empire with so great a stake in the tropics.

Dr. PATRICK MANSON said the object of the school was to educate medical men who proposed to practise in the tropics. Another function was to attempt to advance the science of medicine in regard to tropical diseases. Mainly through the assistance of Mr. Chamberlain and of the managers of the Dreadnought Hospital the initial financial difficulties and professional opposition had been overcome. The number of students was so numerous that they could not admit them because the accommodation was too scanty. A growing institution should not be choked by a superfluity of work thrown upon it. There was a danger that students coming to them and finding no room might go elsewhere or give up the idea of special education in tropical diseases. The students were no callow youths—they were men of experience, many of them with grey hairs. The space at their disposal did not suffice to accommodate the students. They wanted enlarged laboratories, a lecture-room, a museum, and a library. Funds were appealed for on the strength of the work that was done by students of the school. One of them, Dr. George Low, discovered in the West Indies that over 11 per cent. of the inhabitants of Barbadoes were the subjects of the peculiar blood parasite causing elephantiasis, and had shown that by simple and inexpensive sanitary measures that disease and its associated condition were capable of absolute eradication in the course of a generation. Dr. H. E. Durham who was going out on behalf of the school to study disease in the South Pacific was the same gentleman who went out to Brazil with Dr. W. Myers to study yellow fever. Both contracted yellow fever and Dr. Myers died. When men like these were ready to lose their lives in the cause of science and humanity there should be no difficulty in finding funds for these researches. The English Government were very niggardly in these matters when compared with the German Government. Professor Koch had written giving particulars of subsidies granted to the following German medical expeditions by the German Government: (1) Professor Frosch in Brioni (Istria), (2) Staff-Doctor Bludau in Lussinpiccolo (Istria), (3) Staff-Doctor Vagedes in German South-West Africa, (4) Staff-Doctor Dempwolff in New Guinea, (5) Staff-Doctor Ollwig in German East Africa, (6) Dr. Krulle in the Marshall Islands, and further expeditions to Togo and Kameruns were being planned. Members of European expeditions received a daily allowance of £1 besides travelling expenses and allowances, and those on foreign expeditions £2 daily with allowances and special grants for personal equipment.

Sir FRANCIS LOVELL, C.M.G., late Surgeon-General of Trinidad, said that he had undertaken an expedition to the tropics on behalf of the Seamen's Hospital Society in order to provide funds to enable that society to put the London School of Tropical Medicine in a more satisfactory financial position. It was absolutely necessary that funds should be forthcoming, and it was felt by the Seamen's Hospital Society that an appeal should be made to those resident abroad. He had offered to the society to go abroad to induce the English residents in the East and in other tropical parts to contribute towards the objects which the school had in view. It had been decided that he was to go to India, to Ceylon, to the Straits Settlements, to China, to Japan, to New Zealand, and to Australia. He would return home probably by way of the United States and Canada. His intention was to raise funds to enable the society to put the London School of Tropical Medicine on such a footing as would make it worthy of its name as a teaching body in the great city of London.

**SEWERAGE AGREEMENTS.**—At the Plymouth County Court on Oct. 18th the St. Germans Rural District Council recovered £5 from a builder for connecting two houses with the public sewer. The case involved the validity of agreements under which the council exact from builders a contribution towards the cost of sewer extension.

## THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1900.

### III.

#### CONCLUDING NOTICE.<sup>1</sup>

IN the second notice of this report a considerable space was occupied in giving an account of lead-poisoning as it occurs in the various industries in which the metal is used, and the means which the inspectors have adopted to lessen the evil. The other poisonous metals have caused fewer cases of poisoning, and, important as they are, it is fortunately not necessary to dwell upon them in any great detail.

The number of cases of mercurial poisoning contracted in factories and workshops during the year was nine. With a single exception all the sufferers were men. The one woman affected was a "manufacturer of jellies"; the exact occupation in which she was engaged was that of "quicksilvering trays," a process carried on once or twice during the year, and it need only be added that the case was a slight one. Of the men three were manufacturing chemists, one was employed in alkali works in a process for the recovery of mercury, one was a thermometer-maker, one was a maker of electrical metres, and one was a glass-silverer. It was found by the inspectors that in factories in which calomel, corrosive sublimate, and red oxide of mercury and vermilion are made a proportion of no less than 15 per cent. suffered from salivation and over a third from tremors. The number of men examined was, however, small—27 in all. The chief danger of poisoning occurs in the volatilisation of the metal which occurs in the process of sublimation. Special rules have been drawn up for the use of the workers in trades in which mercurial preparations are made, and these rules have, in the case of two factories, been voluntarily adopted. The rules include the appointment of an examining surgeon, the provision by the manufacturers of overall suits, respirators, washing facilities, including baths with hot and cold water constantly laid on, and the use of a cloak-room. The workers are forbidden to take food or tobacco to the factory. It has been found that the makers of electric metres suffer to a considerable extent from mercurialism, and in one case, in which an increase of business necessitated the building of a new factory, the firm were glad to avail themselves of the valuable information which was afforded to them by the medical inspector both in regard to the improvement of the structure of the factory and the conditions under which the business would, from a hygienic point of view, be best carried on. It is in this quiet way that much of the most useful work done by the medical officers of the Home Office is carried out, without litigation and without publicity. And thus it often happens that the best work is often that least appreciated.

During the year an investigation was made into the condition of those who worked at the process in use by hatters for the preparation of the fur—a process in which nitrate of mercury is used. A circular letter on this matter was sent in January of the present year to the manufacturers engaged in the business by the chief inspector (Appendix 15). In this letter Dr. B. A. Whitelegge pointed out that the precautions of primary importance which should be adopted for the protection of the workers are: (1) the removal of the fumes and dust; (2) periodical medical inspection by an officer having power to suspend the workers from their occupation; and (3) facilities for washing.

Seven cases of arsenical poisoning, all of which occurred in women, were reported from a factory in which "emerald green" is manufactured, and at which 25 women were working. This salt is used chiefly for the destruction of the insect pests which destroy fruit trees and potatoes; the business, therefore, is a fluctuating one. The special incidence of the poisoning in the case referred to was, in the opinion of the medical inspector, due to the defective working of the fan which should have removed the dust produced in the process of packing. 13 cases, of which three were fatal, were reported of poisoning from arseniuretted hydrogen. One of these cases is recorded in considerable

<sup>1</sup> The first and second notices appeared in THE LANCET of Sept. 28th (p. 886) and Oct. 12th (p. 998), 1901, respectively.

detail (pp. 459-462). A cautious Scottish jury found that the cause of death was "from poisoning contracted (by the deceased) in the course of his employment." The opinions of scientific experts differed, and apparently still differ, as to the nature of the fatal gas and the means by which it was generated in this case.

The total number of cases of anthrax reported during the year was 37, of which seven were fatal. Of these cases 12 (of which three were fatal) occurred in people engaged in the handling of horsehair, and of the sufferers five were men, two were women, and five were "young persons" (three males and two females). Nine cases (of which two were fatal) occurred amongst wool-sorters and nine (one of which was fatal) amongst tanners and fellmongers, part of whose business it is to handle and sort hides and skins. The remaining seven cases occurred amongst those engaged in other industries. No case occurred amongst wool-combers. For the regulation of this industry special rules (given in the Annual Report for 1899, pp. 57 and 58) came into force in April, 1900. The rules appear to be working well—a fact which the medical inspector ascribes in great measure to the fact that they were the outcome of a conference held between representatives of the Bradford Chamber of Commerce, the Factory Department of the Home Office, and the Bradford and District Trades and Labour Council. Mr. Cecil Duncan, analyst to the County Council of Worcester, in conjunction with, and by means of apparatus provided by, a firm of hair and carpet manufacturers at Worcester, has carried out a number of experiments to test the efficacy of a well-known steam disinfectant in regard to its use in sterilising infected China mane hair. The experiments appear to have been conducted with the greatest possible care. The conclusions to which Mr. Duncan has come throw great doubt on the accuracy of deductions drawn from the experiments of Dr. Kubler,<sup>2</sup> whose report to the German Health Office has apparently been estimated at a higher value than its intrinsic worth warranted. Dr. Kubler's experiments were made with laboratory specimens which he introduced into bales of hair. Mr. A. Webb has made experiments in which the material used contained the spores of anthrax in their natural environment on the hair, dry and surrounded with dirt and grease. What he actually found was that so long as the steam was kept away from the spores a high temperature alone was not effective in killing them. Unfortunately, steam is very prejudicial to hair from a commercial point of view. It seems possible that no effective method has yet been discovered of thoroughly freeing hair from the spores of anthrax without injury to the material which contains them. The best method of efficient disinfection of merchandisable commodities from such a dangerous poison as that of anthrax is not an unfit subject for inquiry by the medical officers of the Local Government Board.

Attention was lately prominently called by Dr. Birmingham to the great mortality which occurred amongst those engaged in the "ganister" industry. Ganister is a close-grained hard silicious stone and contains from 75 to 95 per cent. of silica. It has a greater fire-resisting capacity than any other known substance and is therefore used for lining the bottom of crucibles and of Bessemer converters. The stone is obtained by blasting with dynamite; it is afterwards crushed by an instrument specially devised for the purpose and is finally ground in the presence of water and moulded into bricks. The miners suffer greatly from the inhalation of the dust and frequently die from a disease which has for years been known as fibroid phthisis and to which in the case of stone miners the term "silicosis" has more recently been applied. Dr. Birmingham in the paper which he read at the Sanitary Institute in the year 1899 stated that the annual average death-rate which occurred amongst ganister workers amounted to 22.29 per 1000 workers.<sup>3</sup> Commander Smith on behalf of the Home Office has made an inquiry into the working of the ganister industry and Dr. F. W. Andrewes has investigated the pathological conditions which exist in the lungs of a typical case of silicosis, and a chemical analysis conducted by Mr. H. A. Schöberg shows that a large quantity of silica was contained in the substance of the lung. The report contains some good coloured illustrations of the pathological appearances. Mr. J. Hilditch, inspector for North Wales, who gives an excellent account of the manufacture of silica and fireclay goods, and who writes with the knowledge which is to be obtained only by long experience, has drawn up some suggestions which are likely to be of use if they are efficiently carried out.

<sup>2</sup> Arbeiten aus dem Kaiserlichen Gesundheitsamte, vol. xv., Heft 1.

<sup>3</sup> Journal of the Sanitary Institute, vol. xxi., part 1.

They are all designed to prevent the inhalation of the noxious dust, and it is not necessary to do more than refer to them in terms of praise.

The sectional report of Mr. W. Williams, the inspector under the Cloth Factories Acts, deals not only with the administration of the control of the working of cotton mills, but includes also the administration of special rules for flax and linen factories which are engaged in damp ("humified") processes of work. During the year 1900 the number of rooms from which humidity returns were received amounted to 1476; of these, 1217 were in England, 16 in Scotland, and 243 in Ireland. Of the English counties Lancashire is the great centre of the cotton industry, and 902 returns were received from that county alone. Of this number one only was from a worsted mill and five were from flax mills. In the West Riding of Yorkshire of 166 returns 71 were from cotton mills and 91 were from wool and worsted mills. The flax-spinning industry is carried on chiefly in Ireland. Of 170 rooms used for this trade 10 only exist in England, nine in Scotland, the remaining 151 are all in Ireland, and of these no less than 101 are in the county of Antrim. The chief work of Mr. Williams has been that of enforcing the regulations issued by the Secretary of State under the Cotton Cloth Factories Act, 1897. Of this work the supervision of the ventilation of weaving-sheds has been the most important, and this for more than one reason. In the first place, the intrinsic importance of the subject demanded that it should have prime consideration, but this reason alone would not have sufficed had the regulations been ambiguous in their phraseology. But the regulations "for the first time in the history of factory legislation arrived at a scientific standard of ventilation based on the actual purity of the atmosphere breathed by the workers." The impurity of the air was to be judged by the proportion of carbonic acid present in the air of the shed. The regulation, it may be remembered, was made after an inquiry by a committee which included Sir Henry Roscoe, Dr. Ransome, and the late Sir William Roberts. It was as follows: "The arrangement for ventilation shall be such that during working hours in no part of the cotton cloth factory shall the proportion of carbonic acid (carbon dioxide) in the air be greater than nine volumes of carbonic acid to every 10,000 volumes of air." The committee pointed out that the standard amount of carbonic acid permitted by this regulation was a high one, but that they anticipated that the adoption of the regulation would, notwithstanding that objection, be of service. So it has proved. The greatest good which is likely to follow is the precedent which has been formed for the adoption of a definite and easily determinable standard of permissible impurity in the air breathed by workmen. To show the amount of improvement which has already been effected the inspector gives a table based upon tests made in 35 weaving-sheds during the year 1900. The table shows in each of the 35 cases the number of volumes of carbonic acid per 10,000 volumes of air: (1) before the improvement in ventilating arrangements was effected; and (2) after improvement in ventilating arrangements was effected. The actual improvement effected is, however, most easily realised by comparing two other columns of figures which have been added to the table (see C and D in the tabular statement given below). The figures in these columns are obtained by deducting from the amount of carbonic acid experimentally found to be present in the workrooms the amount normally present in the outside air of manufacturing towns—an amount which is approximately estimated as four volumes per 10,000. The figures in these last two columns therefore give a tolerably accurate indication of the respiratory impurity present in the air before and after improvement was made in the ventilating arrangements. The average of the 35 cases is as follows and the improvement will be most easily seen in a tabular form:—

Number of volumes of carbonic acid (CO <sub>2</sub> ) per 10,000 volumes of air.		Approximate number of volumes of CO <sub>2</sub> per 10,000 due to respiration.	
Before improvement in ventilating arrangements.	After improvement in ventilating arrangements.	C. Before improvement in ventilating arrangements.	D. After improvement in ventilating arrangements.
13.0	7.9	9.0	3.9

These results, which affect more than 6000 workers, show

that an enormous amount of good has been effected, and in some cases it may be mentioned that the amount of respiratory impurity has been diminished by more than two-thirds. The inspector mentions one case in which a firm of cotton manufacturers have introduced a system of ventilation by which the amount of carbonic acid present in their sheds has been reduced to the extent of from 5.6 to 6.7 volumes per 10,000 volumes of air. Such an instance is unfortunately not a common one, although opposition to sanitary improvements is becoming less marked on the part of manufacturers as they are learning that improved health conditions amongst the workers leads to better work. In the past the atmospheric pollution present in the workshops has been appalling and has been quite sufficient to account for the low standard of physique which has been commonly remarked as usual amongst cotton-spinners. Unfortunately, the regulation which we have quoted in regard to the permissible amount of carbonic acid impurity refers only to the air of the artificially moistened sheds in which the weaving of cotton cloth is carried out. No such regulation is in force in the case of rooms used for cotton-spinning. The atmospheric condition of many of these rooms must be a fertile source of disease. A table given showing the amount of carbonic acid in some of these mills is most striking. We must be content to quote a few cases only.

No. of case.	Process.	Space per head in cubic feet.	Temperature in degrees Fahrenheit.	Number of volumes of CO <sub>2</sub> per 10,000 volumes of air.	Remarks.
2	Spinning.	9,000	85	24.2	No mechanical means of ventilation.
3	"	8,500	86	33.5	
7	"	10,000	92	28.1	
8	"	10,000	85	32.2	
9	Carding.	4,000	80	10.2	

The cotton mills in which these investigations were carried out are situated at Bolton and "from a structural point of view" are said to be not bad specimens of their class. Mr. Williams remarks that he thinks that most intelligent observers will be convinced that there is a great waste of human life and energy owing to the defective supply of fresh air to indoor workers. At the present time very many of the cotton-spinners' sheds have no mechanical means of ventilation. The temperature of the air in some of the sheds is much higher than it should be. In the table above quoted it will be noticed that in one case (No. 7) the temperature was found to be 92° F. In another case, which is omitted from the list which we have taken, the temperature was also 92° F. and in a third case it was 91° F. The regulations of the Secretary of State stipulate that the steam used for moistening the atmosphere of workmen's sheds must be obtained from pure water—a regulation rendered necessary by the knowledge that it had previously been occasionally the practice to obtain the steam from water which was polluted by the remains of decaying animals or by sewage. Flax mills and linen factories have been placed under special rules in regard to their management since the year 1896. These regulations have regard to the control of weaving-sheds, wet spinning-rooms, roughing-rooms, sorting-rooms and hand hackling-rooms, carding-rooms, and dressing-rooms. The rules, which are given *in extenso* in the report (pp. 422-423), have been of great use, but the inspector finds that conditions still exist which are dangerous to health. In the wet spinning-rooms the workers, especially the children, have their clothes wet through by the spray. The atmosphere, which has frequently a temperature of over 70° F., often contains more moisture than the amount legally allowed in the case of cotton mills. The compulsory special rules are not at present applied to wet spinning-rooms and in some cases the steam is generated from very impure water. Mr. Williams in concluding his report advises that a special inquiry should be made into the sanitary condition of flax and linen factories, with especial reference to the following subjects: (1) the protection of workers from dust; (2) the ventilation of all departments, particularly the reeling-rooms, wet spinning-rooms, and weaving-sheds; (3) the prevention of excessive humidity and temperature in wet spinning and weaving; (4) the protection of workers in the wet spinning-rooms from getting wetted by

the spray from the frames; (5) the prohibition of the use of impure steam or impure water for moistening the air breathed by the workers; and (6) the reduction of the temperature of dressing-rooms. The chief inspector, we are glad to see, announces that arrangements are being made for such an inquiry.

The report of the engineering adviser, Mr. E. H. Osborn, is concise and is clearly written. Mr. Osborn gives considerable prominence to the regulations in force in some of the United States of America. The rules are, as he remarks, "notable for perspicuity of specific detail and comprehensiveness." It is, however, much easier to begin in a new country with new rules. There are fewer organised trade interests to fight. The difficulties which have arisen in England have often been caused by a seeming injustice in interfering with long-established customs of trade. Yet it will be admitted by all right-minded people that "it hardly seems consonant with sound policy that an employer should claim a sort of vested interest in subjecting his workmen to unhealthy conditions because his machines are badly arranged." Mr. Osborn suggests that injurious dusts should be scheduled and that the list should be added to as research makes clear the mischievous nature of those not already in the list. This proposition seems from every point of view to be commendable.

Mr. A. G. H. Thatcher, His Majesty's Inspector's Assistant, gives a most valuable report on accidents occurring on buildings in course of construction or repair (Appendix 10, p. 97). He explains the causes of the occurrence of those accidents which may be considered "controllable"—that is to say, avoidable by builders and workmen. He deals briefly with the mishaps for which the architect is responsible—accidents which, he points out, are "generally owing to erratic or miscalculated formulæ." The report is quite short and consists of three pages only, with an appendix of one page of illustrative drawings. It contains an enormous amount of condensed information in regard to scaffolding and the lifting and carrying of ironwork, timber, bricks, slates, and stone. The illustrations are excellent. The one on scaffolding shows at a glance the true theory of scaffold-building and gives the technical names of the various parts and processes adopted. A copy of this report should be in the hands of all builders.

It may be of use to mention the appeal cases which were of interest to the Home Office and which were decided during 1900. They were as follows: Squire v. Sweeny (High Court of Justice in Ireland, Queen's Bench Division), Jan. 16th, 1900; Squire v. Sweeny (High Court of Justice in Ireland, Queen's Bench Division, Crown side), June 27th, 1900. In the first of these cases it was decided that the Act 41 Vict. c. 16, s. 68 (4) does not confine the place at which inquiries and examinations under it are made to the place where work is given out to out-workers or to the factory or workshop itself. Tracey v. Pretty and Sons (1901, 1 Q. B. 444), Hoare v. Ritchie and Son (1901, 1 Q. B. 434). In this case it was held that it was not necessary in order that a conviction should be obtained under Section 36 of the Factory and Workshop Act, 1878, to prove that any worker had sustained actual injury from inhaling dust, but that it was sufficient if it was proved that dust was generated and inhaled by the workers to an extent that must in the long run be injurious. Bennet v. Harding, High Court of Justice (Queen's Bench Division), June 14th, 1900. In this case it was held that stables and stable-yards were a workplace within the meaning of Section 38 of the Public Health London Act, 1891, and that as cab-drivers were in attendance there sanitary conveniences must be provided for them.

Commander H. P. Smith in his report on the manufacture of wall-papers (Appendix 9, p. 83) gives a most interesting account of the business. The report, he points out, is to be considered as supplementary to that of the Departmental Committee on Dangerous Trades.

During the year some correspondence took place between the Home Office and the Irish Agricultural Society on the subject of the management of creameries in Ireland (Appendix 11). This industry is a very important one, and it is to be hoped that it will not be unreasonably hampered by restrictions. The attitude of the Irish Agricultural Society cannot be clearly ascertained from the correspondence published, for a circular which forms part of their case does not appear in the report.

The number of accidents reported by certifying surgeons as due to locomotives registered from July 1st to Dec. 31st,

1900, amounted to 178 (Appendix 19). Many of the accidents were caused in the process of shunting. No fewer than 238 injuries were reported during the same period as having been caused by grindstones (Appendix 22).

The report of Miss A. M. Anderson, His Majesty's Principal Lady Inspector of Factories, which has already been incidentally referred to, compares in one important point very favourably with that of the chief inspector. It is provided with a well-arranged table of contents, so that it is possible without loss of time to refer to any point which may be of interest to the reader.

## THE FIFTH INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.

HELD AT TURIN, SEPT. 17TH-21ST, 1901.

THE following are some further abstracts of communications made to the above Congress:—

### *Gustatory Sensations in the Larynx.*

Dr. F. KIESOW (Turin) read a paper on the above subject. He said that Michelson and Langendorff had found that the posterior surface of the epiglottis (in whose mucous membrane taste-buds were found) gave a positive reaction of taste to solutions of quinine and saccharin and to the electric current. Dr. Kiesow was able to confirm this and in addition found that all the four recognised modifications of gustatory sensation—acid, saline, sweet, and bitter—were also present. The intensity of the sensation was much less than in other taste regions and some of the "tastes" were confused. He himself could not distinguish between acid and saline with certainty. The inner surface of the larynx was also found to be sensitive in one experiment upon himself, but neither acids nor the electric current were tested. To carry out this latter experiment it was necessary to paint the epiglottis with solutions of cocaine and gymnemic acid. A sound was then passed (aided by the laryngoscope) to apply the solutions. In the investigation Dr. Kiesow was assisted by Dr. Hahn.

### *Stomach Movements in Different Animals.*

Professor GRÜTZNER (Tübingen) said that these were studied by feeding animals (mostly rabbits) on the same diets and killing them at different periods after administering the food. The chopped-up meal was coloured with a substance prepared from the fruit of the bilberry (*vaccinium myrtillus*), which was bluish-green in alkaline fluids, but turned red when acidified. The stomachs were quickly removed from the animals, after being ligatured at both ends and rapidly frozen through. Transverse and longitudinal sections of the organ were then made. After digestion had fairly set in the pyloric funnel was always found filled with acidified and well-digested food. At the cardiac end the food was acid only at the surface, never in the interior of the mass. Fluid food, however, when brought into the stomach after a long period of fasting rapidly came into contact with the mucous membrane, was acidified, and then passed on to the pylorus. Solid or semi-solid food, on the other hand, was conducted into the interior of any food already in the organ—and rabbits' stomachs were rarely empty—only slowly reaching the mucous membrane to be acidified and digested. What happened generally, appeared to be as just related in the foregoing sentence, the food after gaining the surface of the mucous membrane being driven along both curvatures from cardia to pylorus and only when digested allowed to enter the pyloric funnel. Localised contractions were observed which might have served this purpose or possibly might have been the cause of the so-called rolling movements which were supposed to account for the formation of "balls" in the stomach.

### *The Excretion of Bile on Various Diets and after the Subcutaneous Injection of Certain Food Materials in Solution.*

Dr. BARBERA (Bologna) contributed a paper on the above subject. The experiments were performed on dogs with complete permanent biliary fistulae. It was found in agreement with others that proteids caused a marked increase in the elimination of bile, extending over a considerable period; an equal quantity of fats produced a less increase but of longer duration. Carbohydrate food, however, caused exceedingly little augmentation and only for a very short

time. Mixed diets produced effects which varied but which harmonised with the proportion of one or other of the foregoing ingredients in the mixture. Water produced no influence. The period of latent effect was shortest (from 20 to 30 minutes) after meals of proteids, carbohydrates, and of mixed ingredients, and longest (from 50 to 60 minutes) after fats. The maximum rate of outflow was reached from two to three hours after carbohydrates, from three to four hours after proteids, and from five to seven hours after fats. Subcutaneous injections of 10 per cent. solutions of glucose increased the elimination slightly, but the effect soon passed off. Similar solutions of somatose had a greater and more lasting effect. Oil injected under the skin had no influence.

### *The Action of Succus Entericus on Pancreatic Juice.*

Dr. A. WALTHER (St. Petersburg) said that it was known that a ferment had been discovered in the succus entericus by Pawlow and one of his pupils, which had the effect of markedly augmenting the proteid-digesting power of pancreatic juice. A demonstration of the influence of this ferment (named enterokinase) upon the digestion of fibrin was made by Dr. Walther whose further investigations went to show that it only increased the power of fresh pancreatic juice which contained a considerable proportion of its ferment in the form of zymogen. The enterokinase rapidly converted the zymogen into trypsin. In this process oxidation played no part and hence the zymogen of the juice must be different from Heidenhain's zymogen obtained from the gland. A proteid body could be precipitated from fresh pancreatic juice in considerable quantity with dilute hydrochloric acid (0.5 per cent.), which was neither trypsin nor its zymogen. These remained in the filtrate, the whole of the zymogen of which could readily be converted into trypsin by submitting it to dialysis. This was shown by the fact that its activity was thereby greatly increased and could be no further augmented by the addition of kinase. The action of the kinase was probably therefore one of hydrolysis. Fresh pancreatic juice had also its digestive power increased by dialysis. During dialysis of the filtrate from the HCl-precipitate, a proteid body, possibly of a globulin nature, often separated out. This body very strongly digested proteids, but had little or no influence on starch. The fluid out of which it separated digested starch with great ease, however, and also to some extent proteid. This fact was of interest since it showed that in dialysis a means was at hand for separating the tryptic from the amylolytic ferment.

### *Does the Spleen Play a Role in Pancreatic Digestion?*

Professor DELEZENNE and Dr. A. FROUIN, in a paper under the above heading, stated that the old theory of Schiff, that a substance indispensable for the pancreatic digestion of proteids was formed in the spleen, though denied by many, and displaced by Heidenhain's discovery of a tryptic zymogen, had recently been revived by Herzen and Gachet and Pachon. The latter observer believed that the splenic substance or ferment played the rôle of converting the zymogen into zymase (trypsin), thus setting it free to work. Dastre, however, had shown that removal of the spleen in no way altered the health of the animal or prevented the full development of young animals. Professor Delezenne and Dr. Frouin thought this experiment hardly sufficient to settle the theory one way or the other. Accordingly they attempted the solution of the question as follows. The stomach was isolated in dogs by joining the lower end of the œsophagus with the upper end of the duodenum. It was possible to accomplish this without injury to the vagi nerves. Both ends of the stomach were then closed and a fistula made into it through the wall of the abdomen, by means of which gastric juice was drawn off once a day. In other cases the stomach was wholly excised. The animals recovered well from these operations and their feeding presented no special difficulty. After recovery the spleen was excised and again without permanent interference with health. In such animals digestion of proteids was wholly performed by the pancreas and yet removal of the spleen produced no trouble whatever. The dogs not only lived but enjoyed the best of health, and one of those with an isolated stomach was exhibited at the congress six months after the second operation. Further, the juice secreted by the stomach was perfectly normal. Professor Delezenne and Dr. Frouin therefore concluded that the spleen could play no indispensable rôle in pancreatic digestion. Its influence on this process was quite insignificant when contrasted with that of Pawlow's entero-kinase.

*The Origin of the Pepsin found in Urine.*

Professor DELEZENNE and Dr. A. FROUIN had also made use of the animals employed in the foregoing research to determine the source of the peptic ferment which was normally found in urine. The zymase was present most abundantly in the morning urine and that secreted between meals. During the height of digestion it was absent. These facts suggested the idea that the ferment of the urine was the same which had been employed in digestion and which was afterwards absorbed to be got rid of by the kidney. In support of this it was found that the urine of dogs from which the stomachs had been removed never yielded any pepsin; that of the animals in which the organ was merely isolated, on the contrary, always contained it. It was permissible, therefore, to conclude that the urinary pepsin had its origin in the stomach and was also absorbed from the same organ. It seemed of interest to determine whether absorption likewise occurred from the bowel. Normal gastric juice was therefore given to an animal without a stomach, but no ferment was ever found in the urine, consequently Professor Delezenne and Dr. Frouin supposed that this did not take place in health. It was more probable that the ferment was destroyed in the intestine.

*The Absorption of Sugars from the Intestine in Relation to the Osmotic Tension of their Solutions.*

Professor ALBERTONI (Bologna) said that he had found that the rate of absorption of sugars did not correspond with the osmotic tension of the substances in solutions. Of solutions of glucose, saccharose, and lactose of the same osmotic tension the amount absorbed of the two former was greater than that of the latter. The same difference was maintained even when the osmotic tension of the lactose solutions was altered—i.e., made higher or lower than that of the others. The absolute quantity of substance absorbed was, however, always greater with hypertonic than with isotonic or hypotonic solutions. When hypertonic solutions of the sugars had been administered by the stomach the osmotic tension of the liquid found in its cavity an hour later was always reduced, though greater than that of the blood. On the contrary, with isotonic and hypotonic solutions an increase of osmotic tension occurred. In this connexion it was of interest to remark that the osmotic tension of the liquid normally found in the intestine was practically constant and always higher than that of the blood. During absorption the osmotic tension of the blood underwent slight variations, being augmented somewhat when hypertonic solutions were brought into the intestine. Professor Albertoni concluded that while the laws of osmosis certainly played a part in the process of absorption, especially from the stomach, they did not suffice to explain the whole matter. Experiments which he hoped to publish shortly went to show that the colloidal properties of the blood played a more important rôle.

*The Absorption of Mono- and Di-saccharides from the Intestine.*

Dr. NANGANO KIOTO contributed a paper on the above subject which was communicated by Professor F. ROHMANN (Breslau). The experiments had been performed on dogs with Vella's intestinal fistula. Similar quantities of solutions of the same strength of hexoses (glucose, galactose, mannose, and fructose), and of pentoses (arabinose and xylose) were injected into the bowel and the quantity of each which had disappeared in one hour determined. It was found that unlike quantities of the different stereoisomeric sugars were absorbed, from which it must be concluded that the process was not wholly dependent upon osmotic pressure but that other properties of the substances (in the foregoing cases probably configuration of the molecule) came in. The absorption of di-saccharides was also investigated. These, as was known, were for the most part cleft into mono-saccharides before being taken up; but a greater or less quantity in Dr. Kioto's experiments must have been absorbed unchanged, the activity of the intestinal ferment having been insufficient to have effected their cleavage within the time. It was therefore concluded that the process was continued on their way through the mucous membrane, extracts of which yielded solutions capable of transforming the sugars in question.

# Looking Back.

FROM

THE LANCET, SUNDAY, OCTOBER 26, 1823.

*Ventilation.*

THE following, taken from the History of the Dublin Lying-in Hospital, shows in an extraordinary degree the advantages that result from free ventilation. We consider this a document of great value, and hope that it will convince all parents of the folly, not to say cruelty, of confining young infants in rooms with closed doors and windows.

*Dublin Lying-in Hospital.*—In this hospital 2,944 infants out of 7,650 died in the years 1782, 1783, 1784, and 1785, within the first fortnight after their birth, that is nearly *one child* out of every *six*. They almost all died in convulsions, of what the nurses called *nine-days fits*, because they came on within nine days after their birth. These children, many of them, foamed at their mouths, their thumbs were drawn into the palms of their hands, the jaws were locked, the face was swelled and looked *bluc*, as though they were *choaked*.

This last circumstance led the physicians to conclude that the rooms in the hospital were too *close* and *crowded*, and hence that the infants had not a sufficient quantity of *good air* to breathe. They contrived, therefore, *air-pipes*, six inches wide, which were placed in the ceiling of each room. Three holes, an inch wide, were bored through each window frame; and a number of holes were made in the doors at the bottom.

Thus the rooms were kept *sweet* and *fresh*; and the consequence has been, from the register in that hospital, that,

## Children.

In 1786, out of 1,372 there died	51
1787, — 1,375 ————	59
1788, — 1,496 ————	55
4,243	165

So that since the alteration of the rooms as to airiness, out of 4,243 there died 165 children; whereas before, the average amount of deaths from the same number was 1,632.\*

\* If out of 4,243 children there perish, when the hospital was *ventilated*, only 151 infants, how many may be expected to die out of 7,650, the number of children born in the DUBLIN Lying-in Hospital in the years 1782, 1783, 1784, and 1785? The answer is, by the rule of proportion, 279. But, how dreadful the account, there perished absolutely 4,243, deducting 279, solely from the want of a due supply of *air*! We have not only to deplore the number of innocent victims who were destroyed at this time and previous to it, but also to lament the wretched anguish of the disconsolate parents, and the impoverished state of health in many of the poor babes who survived this slaughter.

The great and good Dr. Hales, whose studies and experiments were constantly directed to the benefit of mankind, recommended a trial of *ventilators* in the SAVOY and NEWGATE prisons, in both of which the *jaill fever* was frequent, and commonly fatal: the good effects exceeded even his most sanguine expectations; for a very small proportion of the sick died, when the ventilators came into use, and the contagion seemed in a manner arrested. The benevolent Mr. HOWARD found the prisons on the continent perfectly free from this *pestilential fever*; owing, as he thinks to the apartments in which the prisoners, were confined being *spacious*, and consequently well aired.

## EPSOM COLLEGE.

WE have frequently called attention to the good work carried out by the Royal Medical Benevolent College in the hope of enlisting for that excellent institution generous support from members of the profession. We now have pleasure in referring to the uninterrupted progress which has attended the educational branch of the association known as Epsom College, which, it is hardly necessary to observe, is quite distinct from the eleemosynary side. Since the foundation of the College by Mr. Probert close upon 50 years ago important additions have from time to time been made to the buildings and land, so that, whereas in the early days only 150 boys could be admitted, there is now ample accommodation for 350 boys. Our readers will be glad to know that some important additions have been made during the last few years, comprising a

lower school for 100 junior boys, a laundry, the enlargement of the chapel, an addition of 15 acres of land, which will prevent undesirable buildings from being erected in close proximity to the College, and an enlarged laboratory and lecture theatre. It is hardly necessary to refer to the value of a separate school for junior boys, since none know better than medical men how desirable it is from many points of view that young boys should be trained away from their seniors. The foundation-stone of the lower school was laid in 1895 by H.R.H. the Prince of Wales, accompanied by their Royal Highnesses the Princess of Wales and the Princess Victoria of Wales. The school is complete in itself and has a separate matron and its own masters.

On Saturday last the Council and other friends of the College met at Epsom to hand over formally to the school the enlarged laboratory and lecture theatre which have been partly built from a legacy of £500 left by the late Mr. P. H. Maddock, a master of the College, who died in 1898. It would be difficult to find any better proof of the value of the work done at Epsom than the fact that a master who was familiar with every detail connected with the school should leave to it all his books and pictures and, in addition, bequeath so handsome a sum to the governing body to be used for the benefit of the College; and the Council could hardly have chosen a more useful way of perpetuating the memory of a master whose heart was always in his work. In arranging the laboratory provision has been made for giving the teacher complete supervision and for preventing students from having occasion to leave their work. Teak benches for 26 boys have been fitted, but there is room for additional accommodation. The arrangement is very compact. There are five double benches for four students, working two aside, and each student has two drawers, two cupboards with knee space between, and two gas-supplies, the taps of which are in front, though the gas points are at the back of the bench. On each side of the bench there is a sink and there is one water-tap with two side leads for every two students. At the end of each bench there is a fume cupboard with sliding, counterpoised doors accessible from both sides of the bench. The shelves for reagents are lined with glass plates. At one end of the room there is a similar bench for six students, with a fume cupboard at each end, and at the other end of the room there is a teak bench for general work, a slate bench with hood over for furnace work, and distillations, and a general sink with a draining-board. The waste from all sinks is conveyed by means of open channels under the floor to the gully outside. Over each bench there is a double gas bracket, which thus gives one burner to each student. Sulphuretted hydrogen is made in two generators and is laid on to each fume cupboard.

As to the educational successes of the College we have frequently referred to them. In three recent years 10 scholarships or exhibitions ranging in value from £30 to £80 and one sizarship of £30 were gained at the Universities of Oxford and Cambridge for classics, mathematics, science, and history. The results of examinations held by the University of London and by the Oxford and Cambridge Schools Examination Board have been exceedingly satisfactory. At the London Matriculation Examination 48 boys have passed during the past three years, including one in honours, and 18 boys have passed the whole of the Preliminary Scientific Examination and 11 others part of it. At the Joint Universities' Examinations 29 higher certificates and 108 lower certificates have been obtained during the same period. For those boys who contemplate medicine as a profession it would be difficult to find a school which offers so many advantages as are offered by Epsom College. There are no fewer than nine medical scholarships of from 120 guineas to £150 in value at the hospital schools in London, and of 15 other scholarships or exhibitions offered five are of £15 in value, two are of £21, two are of £27, one is of £30, another is of £40, two are of £50, and two are of £60. As the College is recognised as a school of science by the Committee of the English Conjoint Board boys are prepared for Parts I. and III. of the first examination. The school fees are very moderate when compared with those charged by schools of the same class. The ordinary fee is £70 a year, but all sons of medical men are allowed a rebate of £10 and a few sons of medical men in reduced circumstances are admitted at £31 10s. a year. The Council offer annually entrance scholarships of £30 a year, open to all comers, and are anxious that the College should not be considered as

exclusively for the sons of medical men, since they are convinced that "class" schools are undesirable. Fifty of the boys are Foundation scholars and they are boarded, clothed, and educated free of charge, the whole cost being borne by the charitable side of the institution.

## THE GENERAL MEDICAL COUNCIL: ELECTION OF DIRECT REPRESENTATIVES, 1901.

MR. GEORGE BROWN'S ADDRESS TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

FELLOW PRACTITIONERS,—As the term for which you elected Dr. Glover and myself in 1896 to represent you in the General Medical Council will expire on Jan. 1st next, you will shortly be called upon to fill the seats which will thus become vacant. I beg to inform you that it is my intention to offer myself for re-election and I venture to hope that my efforts to serve your interests during the four and a half years I have had the honour to represent you will insure me a renewal of your confidence.

It will be in the recollection of many of you that at the last election I pledged myself, if successful, to do my utmost to carry out a definite line of action in regard to five questions of great importance as affecting the well-being of the profession. Respecting these, it may be convenient if I as briefly as possible report progress.

1. *Amendment of the Medical Acts with a view to the suppression of unqualified practice.*—As yet it has been impossible to persuade the Council to take action in favour thereof, but as some of the most powerful opponents of medical reform have during the last year or two ceased to be members of the Council and their seats are now occupied by others whose views are more in harmony with those held by the bulk of the profession, I am not without hope that medical reform will be regarded with more favour in the future, although some outside pressure may be necessary before the Council takes any practical steps to promote a Bill to amend the Medical Acts in the direction indicated.

2. *To prevent sick clubs and dispensaries whose agents canvass for patients from obtaining the services of registered practitioners.*—It is a great satisfaction to me to know that I have assisted in passing a resolution expressing the disapproval of the Council with those practitioners who associate themselves with clubs whose agents systematically canvass for patients. This resolution is a step in the right direction, but as the expression of a pious opinion it will, I fear, be of little use. The degrading practice can only be suppressed by dealing with it in the same manner as offences which are regarded as infamous in a professional respect. I shall always insist, as I have in the past, that the absence of a wage-limit is likely to lead to the abuse of clubs and dispensaries, as well as to friction and contentions among neighbouring practitioners.

3. *To oppose the Bill for the registration of midwives.*—Through the action initiated by me at the May session, 1897, notwithstanding that the Council had previously in very decided language, to use the late Sir Richard Quain's own words, declined to interfere with the proposed legislation respecting the practice of midwives, the Council appointed a special committee to consider the proposed measure. As a result the Lord President of the Privy Council was informed that the Council "would earnestly deprecate its passing into law." Happily, in consequence of the opposition thus raised, the mischievous Bill did not receive the sanction of Parliament, and I have no fear that it ever will become law if the profession as a whole continues to exercise the vigilance and activity in opposing the measure it has hitherto done. Much will depend upon the votes recorded in this election, and you may rely upon me that my opposition to legalising midwives as independent practitioners will be as keen as ever, and I should like both midwives and all unqualified practitioners made legally responsible for any damage they may cause to mother or child or any other person. I am, however, in favour of legislation to insure the better education and registration of obstetric and other nurses to act under the direct supervision of medical practitioners.

4. *The raising of the standard of medical education.*—In

accordance with my pledges I have worked in harmony with those members of the Council who are in favour of raising the standard of education, and it is satisfactory to report that during the last year or two regulations have been adopted lengthening the course of professional study and raising the standard of preliminary examinations. It is to be regretted that the Royal College of Physicians and the Royal College of Surgeons of England appear disposed to dispute the authority of the Council in regard to this matter. Although I am a Member of the College of Surgeons I feel that in all questions relating to medical education the fiat of the Medical Council should be absolute, and as long as I continue to be a member of that body my action will be guided by a sincere wish to support its authority. Unless the Council's authority be maintained medical education will soon become chaotic.

5. *Increased direct representation.*—On two occasions I have proposed motions calling upon the Council to make application to the Privy Council to obtain additional direct representation for England and Wales, as provided for in the Medical Act of 1886, but I regret to say that on each occasion the proposition was rejected by a large majority. If I continue to represent you on the Council I shall again press this question upon the members, but I fear nothing will be accomplished in that direction unless a direct appeal to Parliament be made. I shall do my utmost, both inside and outside the Council, to assist those who consider that their representatives on it should be elected by the graduates of the universities and the members of the corporations, and not solely by the senates and councils respectively. It is a satisfaction to me to report that during my term of office I have taken an active part in bringing about the promulgation of new regulations respecting the employment of unqualified assistants which have done more to protect the public against unqualified practice and to elevate the profession than any other measure adopted by the Council since the profession has had the privilege of sending Direct Representatives to the Council.

There are other points I would have desired to mention in this address, but must deal with them at the public meetings. I would therefore conclude by thanking you for the generous consideration shown towards me during my term of office, and by giving you the assurance that should you honour me by re-electing me as one of your representatives I shall, as in the past, do all in my power to serve your interests and to uphold the honour and dignity as well as the interests of our profession.

I remain, fellow practitioners, your obedient servant,  
6, Gibson-square, London, N., October, 1901. GEORGE BROWN.

#### MR. GEORGE JACKSON'S ADDRESS TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—Having been invited by the Incorporated Medical Practitioners' Association, in conjunction with Mr. George Brown, to become a candidate as a Direct Representative on the General Medical Council, I have acceded to their request, and am encouraged to do so by the fact that I obtained 4082 votes at the last election, although very late in the field.

On the last occasion, omitting a bye-election caused by the resignation of Dr. Rentoul, the contest turned principally on the question of the registration of midwives, the votes in favour of it being only 8443, as against 26,040. I am now, as then, opposed to the registration of midwives, the creation of an inferior order of practitioners. The only way to settle this vexed question is by the registration of all nurses, who will be obliged to act under the direct control of duly qualified medical practitioners.

The objects which should engage the attention of the General Medical Council in the immediate future should be in my opinion:—

1. The reform of the Medical Acts, so as to provide for direct representation of the medical profession in every case except the Crown nominees.
2. Raising the standard of the entrance examinations and limiting the age of entrance so as not to be under 17 years.
3. The one-portal system of entrance to be secured by forming a Board of Examiners, composed of delegates from the present examining bodies.
4. Such an alteration of the Acts which will give the Council power to suppress quacks, &c., who practise medicine and surgery under various forms of colourable pretences.
5. A more definite pronouncement against medical men

acting as medical advisers to clubs and insurance societies whose agents tout for members.

For the information of those to whom I am unknown personally I may state that I have taken an active part in medical politics for more than 20 years. In conjunction with Mr. Reginald Harrison I set on foot some 20 years ago a movement which had for its object the voting by voting papers for the election of members of the Council of the Royal College of Surgeons, which was successful. About 15 to 16 years ago I endeavoured to establish locally a medical sick assurance society, and thus helped to prepare the way for the society which at present exists, and does such good work. In 1895 I was President of the Incorporated Medical Practitioners' Association, and had previously founded the Devon and Cornwall local branch of the same, which has done good work in checking irregular practice and the like. Last year I was a delegate of the Plymouth Medical Society to the medical organisation meeting at Manchester, and was appointed a member of the committee, which has had a great deal to do with the reform of the British Medical Association.

I have assisted in the work of establishing the Three Towns (Plymouth, Devonport, and Stonehouse) Provident Dispensary in conjunction with the local branch of the Incorporated Medical Practitioners' Association, which works on the principle of a wage-limit, *the management being entirely in the hands of the members of the staff.*

Asking the favour of your vote and interest,

I remain, your obedient servant,

GEORGE JACKSON,

F.R.C.S. Eng., ex-President and Vice-President of the Incorporated Medical Practitioners' Association and of the Devon and Cornwall Branch of the same, and ex-President of the Plymouth Medical Society.

10, Portland-villas, Plymouth, October, 1901.

#### DR. GLOVER.

Dr. Glover has, we regret to learn, lately suffered from a bad eye; he is now, however, much better. We are asked by him to say that he regrets much that, acting under strict medical advice, he is obliged to abstain from attending all public meetings for the present.

He feels confident that his constituents will realise with what reluctance he has to decline invitations from various places where it would be a great pleasure to him to meet them for the discussion of current questions. He ventures to hope that the inconvenience to them will be lessened by the fact that his views have been fully stated and reported on several recent occasions.

#### MR. VICTOR HORSLEY.

When Mr. Horsley was elected a Direct Representative of the profession on the General Medical Council at a bye-election he said that when the next quinquennial election came round he would resign and offer himself for re-election at the same time as the other candidates, thereby saving the profession the expense of multiple elections. He is now legally advised that he cannot take this course, as the wording of the Act places any man who resigns his seat on the General Medical Council in the position of a dead man. A successor must be elected; he cannot himself be re-elected.

## VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6451 births and 3684 deaths were registered during the week ending Oct. 19th. The annual rate of mortality in these towns, which had been 15.6 and 15.9 per 1000 in the two preceding weeks, further rose last week to 16.8 per 1000. In London the death-rate was 16.0 per 1000, while it averaged 17.3 in the 32 large provincial towns. The lowest death-rates in these towns were 10.3 in Derby, 11.1 in Bristol, 11.2 in Croydon, and 11.5 in Huddersfield; the highest rates were 21.9 in Salford, 22.0 in Blackburn, 26.9 in Newcastle, and 28.8 in Gateshead. The 3684 deaths in these towns last week included 467 which were referred to the principal zymotic diseases, against 525 and 485 in the two preceding weeks; of these 467 deaths, 168 resulted from diarrhoeal diseases, 81 from measles, 71 from diphtheria, 59 from "fever" (principally enteric), 47 from scarlet

fever, 30 from whooping-cough, and 11 from small-pox. No deaths from any of these diseases occurred in Croydon or in Derby; in the other towns they caused the lowest death-rates in Cardiff, Swansea, and Halifax, and the highest rates in West Ham, Norwich, Blackburn, Sheffield, and Gateshead. The greatest proportional mortality from measles was recorded in Norwich, Blackburn, and Sheffield; from scarlet fever in Salford; and from diarrhoeal diseases in West Ham, Hull, Gateshead, and Newcastle. The mortality both from whooping-cough and from "fever" showed no marked excess in any of the large towns. The 71 deaths from diphtheria included 33 in London, six in Sheffield, five in Leicester, four in Brighton, three in Portsmouth, and three in Leeds. Eleven fatal cases of small-pox were recorded in London, but not one in any other of the 33 large towns; there were 172 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Oct. 19th, against numbers increasing from 11 to 175 on the 10 preceding Saturdays; 47 new cases were admitted during the week, against 44, 51, and 37 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had risen from 2994 to 3280 at the end of the six preceding weeks, had further increased to 3346 on Saturday last; 407 new cases were admitted during the week, against 460, 426, and 422 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 137, 132, and 186 in the three preceding weeks, further rose last week to 196, but were 72 below the corrected average number. The causes of 39, or 1.1 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Bradford, Leeds, Hull, and in 12 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, Blackburn, and Sunderland.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 14.5 and 16.1 per 1000 in the two preceding weeks, further rose to 16.9 per 1000 during the week ending Oct. 19th, and was slightly above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 11.8 in Aberdeen and 13.4 in Leith to 18.9 in Perth and 22.9 in Greenock. The 537 deaths in these towns included 30 from diarrhoea, 15 from measles, 12 from diphtheria, 12 from whooping-cough, five from scarlet fever, and five from "fever." In all, 79 deaths resulted from these principal zymotic diseases last week, against 82 and 62 in the two preceding weeks. These 79 deaths were equal to an annual rate of 2.5 per 1000, which was 0.4 above the zymotic death-rate last week in the 33 large English towns. The fatal cases of diarrhoea, which had declined from 53 to 32 in the four preceding weeks, further fell last week to 30, of which 11 occurred in Glasgow, five in Dundee, four in Edinburgh, three in Aberdeen, and three in Paisley. The deaths from measles, which had been 12, 14, and six in the three preceding weeks, rose again to 15 last week, and included 14 in Glasgow. The fatal cases of diphtheria, which had been six in each of the two preceding weeks, increased last week to 12, of which seven were registered in Glasgow and two in Greenock. The deaths from whooping-cough, which had declined from 13 to five in the four preceding weeks, rose again to 12 last week, and included eight in Glasgow and three in Edinburgh. The fatal cases of scarlet fever, which had been seven in each of the two preceding weeks, declined last week to five, of which two occurred in Glasgow and two in Greenock. The deaths referred to different forms of "fever," which had been six in each of the two preceding weeks, decreased to five last week, and included three in Edinburgh. The deaths attributed to diseases of the respiratory organs in these towns, which had been 101, 77, and 75 in the three preceding weeks, rose again last week to 97, but were 20 below the number in the corresponding period of last year. The causes of 22, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17.8, 19.9, and 19.7 per 1000 in the three preceding weeks, rose again to 19.9 per 1000 during the week ending Oct. 19th. During the

past four weeks the death-rate has averaged 19.3 per 1000, the rates during the same period being 15.2 in London and 15.6 in Edinburgh. The 143 deaths of persons belonging to Dublin registered during the week under notice were within one of the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 17, 20, and 21 in the three preceding weeks; of these, five resulted from diarrhoea, three from "fever," one from diphtheria, and one from whooping-cough. These 10 deaths were equal to an annual rate of 1.4 per 1000, the zymotic death-rates during the same period being 1.8 in London and 2.0 in Edinburgh. The fatal cases of diarrhoea, which had been 11, 9, and 14 in the three preceding weeks, declined again to five last week. The deaths referred to different forms of "fever," which had been three, eight, and six in the three preceding weeks, further declined last week to three. The 143 deaths in Dublin last week included 36 of children under one year of age and 42 of persons aged upwards of 60 years; the deaths of infants corresponded with the number recorded in the preceding week, while those of elderly persons showed a very marked increase. Six inquest cases and three deaths from violence were registered; and 47, or about one-third, of the deaths occurred in public institutions. The causes of four, or nearly 3 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### REFORM IN THE WAR OFFICE.

THE following statement has been issued by the War Office with regard to the War Office Council.

1. The Secretary of State has directed that in future the War Office Council shall be constituted as follows:—

President—

The Secretary of State for War.

Members—

The Commander-in-Chief.

The Parliamentary Under-Secretary of State.

The Permanent Under-Secretary of State.

The Financial Secretary.

The Quartermaster-General.

The Inspector-General of Fortifications.

The Director-General of Ordnance.

The Adjutant-General.

The Director-General of Mobilisation and Military Intelligence.

The Director-General, Army Medical Department (for medical and sanitary questions).

The Secretary of the Council.

And such other members of the Staff of the War Office as may be specially summoned from time to time.

2. In the absence of the Secretary of State the Commander-in-Chief will act as President.

3. The Council will meet on Mondays, unless otherwise ordered, at 12 o'clock, in the Secretary of State's room.

4. The Council will discuss such matters as may be referred to it by the Secretary of State and any question brought before it by individual members. In order that a *précis* may be prepared notice of the matters for discussion, together with the office papers on the subject, should reach the Secretary not later than the Wednesday evening before each meeting.

5. Records of the proceedings will be kept and copies will be supplied to each member.

In addition to the foregoing there is to be a *Permanent Executive Committee of the War Office*, under the presidency of the Permanent Under-Secretary of State, or in his absence of the Assistant Under-Secretary of State, with certain military and other officials, and the Deputy-Director-General, Army Medical Department, or an officer selected by the Director-General, as members; and the present *Army Board*, of which the Director-General of the Army Medical Service is constituted a member, will be continued. Special departmental committees will also be formed on approval of the Secretary of State for War whenever required, and forward their reports in the first instance marked to the Secretary of the War Office Council.

### ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Staff Surgeon T. J. Crowley to the *President*, additional, for three

months' course for hospital study. Surgeon H. C. Arathoon to the *Vivid*.

#### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel U. J. Bourke is held in readiness to embark for service in Mauritius. Major E. H. Myles is appointed to the medical charge of the Station Hospital at Kasauli and Captain H. A. L. Howell is appointed to the medical charge of the Station Hospital at Khandalla. Captain G. B. Stanistreet, on arrival in the Southern District for duty, is posted to Parkhurst and takes over medical charge of the troops and Station Hospital there from Major A. E. Tate.

Major James E. Nicholson to be Lieutenant-Colonel. Dated Sept. 4th, 1901.

#### VOLUNTEER CORPS.

*Artillery*: 1st Cheshire and Carnarvonshire: Surgeon-Major E. J. Lloyd to be Surgeon-Lieutenant. *Rifle*: 1st Volunteer Battalion the Royal Warwickshire Regiment: Supernumerary Surgeon-Lieutenant A. H. McDougall to be Surgeon-Lieutenant on the Establishment.

#### SOUTH AFRICAN WAR NOTES.

Captain G. S. McLoughlin, R.A.M.C., has been discharged from hospital to duty.

The following are on passage home:—Lieutenant-Colonel J. McLaughlin, R.A.M.C., and Civil Surgeons H. H. G. Knapp, J. A. H. Brincker, and W. J. Moir.

Surgeon Lieutenant-Colonel C. R. Kilkelly, C.M.G., Grenadier Guards, principal medical officer of the Imperial Yeomanry Hospital at Elandsfontein, in his report for the week ending Sept. 26th shows that the total admissions to that branch of the Imperial Yeomanry Hospitals were 294, and that there remained in the hospital at that date seven officers and 116 non-commissioned officers and men. Mr. J. G. Hamilton, the honorary civilian director of these hospitals, in his letter of this week, reports that Messrs. Petersen and Wentworth have added greatly to the brightness of the hospital by sending several wagon-loads of young trees and shrubs, which were being planted round the tents and on the southern boundary of the camp. Numerous other friends had contributed bulbs and flowers, giving the grounds almost the appearance of a horticultural show.

#### AN AMERICAN HOSPITAL SHIP.

In the *Archives de Médecine Navale* for September Dr. Bellot, a senior medical officer in the French navy, gives a highly appreciative account of the American hospital ship *Relief* which he had the opportunity of inspecting recently in Chinese waters. Being himself in medical charge of the *transport-hôpital la Nive* the writer was well qualified for his task and evidently carried it out with great care and minuteness. Originally the *Relief* was built for river and coasting passenger traffic, but when the war with Spain broke out she was converted into a hospital ship under naval management. Capable of steaming 18 knots per hour and with sufficient coal-storage for a voyage between the Sandwich Islands and Japan she was in most respects well suited to her new career, but on the other hand her light draught detracted from her seaworthiness. What seems to have chiefly impressed Dr. Bellot was the spacious loftiness between decks, together with the abundance of light and fresh air which pervaded the whole vessel. The sick were accommodated on two decks reaching from stem to stern, the crew and machinery being established below, and the officers above in a structure which is described as "*une sorte de château*." Almost flush with the water there was "*une immense porte*" capable of admitting laden stretchers with the utmost facility, while internally the numerous channels of intercommunication were thoroughly in keeping. Painted white, with slight gold lines for relief, the interior of the ship, as well as the fittings and appliances, was washable throughout, lending itself readily to efficient disinfection. In the wards there were two layers of beds, one above the other, but each patient had a complete bedside equipment to himself. An apparatus for keeping food cool in summer or warm in winter struck Dr. Bellot as particularly admirable. It consisted of a wheeled receptacle with double walls affording space for ice or hot water according to season. The French officer drank a glass of milk from one of these chests and found it "as agreeable as the most esteemed fresh milk." It came from New Zealand, having been preserved without

either sugar or evaporation, but he regretted that he could not find out the name of the producer. In one of the kitchens that was inspected the cooking was done by electricity. To obtain any required temperature all that was necessary was to press a button. Needless to say, the "sanitary arrangements," as water-closets, baths, &c., are popularly called, were not only excellent, but even luxurious, and that just as much for the rank and file as for the officers; while "everywhere hot and cold water, fresh or salt, circulated on demand." On the upper deck there was an operating-room which with its equipment "approached perfection," and although slightly smaller the research laboratory was supplied with all that could be desired. The *Relief* was entirely under the control of the chief medical officer.

#### SOUTH AFRICAN AFFAIRS.

There is but little to be chronicled in the way of war news. The process of grinding down the enemy's forces is a slow machine-like method. It seems to be the only one, however, that can be pursued under the circumstances. The extent of country over which the war is spread and the numerous independent bodies of Boers in the field and the apparent impossibility of surrounding them and compelling them to fight are the difficulties. The supply problem has become a gigantic one for the War Office in view of the number of our forces in the field, the concentration camps, and the very large number of Boer prisoners who have to look to this country for all they want. The number of lives among the refugees being sacrificed to the exigencies of war in the concentration camps despite all our efforts is pitiful enough, but it seems to be mainly attributable to neglect and ignorance of the most rudimentary laws of hygiene on the part of the Boer population, to the prevalence of epidemic diseases and the extreme difficulty of supplying and preparing suitable food for infants and children. All that can be said is that had the Boer women and children been left to shift for themselves—a course which probably any other nation than England would have taken—the results would have been infinitely worse, although such a policy might in the end have proved a more merciful one. Their natural protectors would not then have been free to fight against us with the knowledge that their families were being all the while taken care of. The sick returns from the seat of war are, as regards British troops, altogether more favourable than they were.

#### WARM CLOTHES FOR RETURNING SOLDIERS.

Major-General the Hon. H. F. Eaton asks us to allow him through the medium of our columns to express his thanks to all those who so generously responded to his appeal from the Soldiers and Sailors Help Society, for clothing for soldiers returning from South Africa, and points out that their special needs at this season are warm overcoats and strong boots, which will be most gratefully received by Captain Simpson, 70, Victoria-street, S.W.; at the employment branch of the Soldiers and Sailors Help Society, 115, Ebury-street, S.W.; at the offices of the Soldiers and Sailors Help Society, 17, King-street, St. James's, S.W.; by Captain S. Waters, 28, Overton-road, Brixton, S.W.; and by Mr. Oliver Williams, 71 and 72, King William-street, E.C.

#### PORTLAND HOSPITAL REPORTS.

Major-General the Hon. Herbert F. Eaton, secretary of the Portland Hospital, asks us to mention that members of the Portland Hospital staff or patients who have passed through this hospital may obtain one of the remaining copies of the reports on remitting 3s. to Mr. Oliver Williams, 71 and 72, King William-street, E.C.

#### ROYAL ARMY MEDICAL CORPS SOUTH AFRICA FUND.

A meeting of the General Committee of this fund will be held to-day (Friday, Oct. 25th) at 5 P.M., at 58, Portland-place, W., to consider the despatch of a Christmas gift to the corps and the closing of the fund. H.R.H. Princess Christian of Schleswig-Holstein will preside.

The King has been pleased to approve of the appointment of Surgeon-General W. Taylor, C.B., to be Director-General, Army Medical Service, and on the retirement, on Dec. 31st next, of Surgeon-General H. S. Muir, C.B., that of Lieutenant-Colonel A. Keogh, C.B., to be Deputy Director-General, with the temporary rank of Surgeon-General.

## Correspondence.

"Audi alteram partem."

## "NOTIFICATION OF INFECTIOUS DISEASE."

To the Editors of THE LANCET.

SIRS,—As my name has been incidentally mentioned by Sir W. T. Gairdner in his letter on the above subject in THE LANCET of Oct. 19th, p. 1074, I trust that I may be permitted to record two instances that strongly support his argument for an amendment of the Notification Act. Five years ago I was called to a young woman, aged 18 years, with a generalised papular rash, a temperature of 103° F., and a history of severe illness for three days. The mother was certain that the patient had measles when a child, so the question of German measles was raised by her. At the time I had only been two years in general practice, so that my experience of infectious and other diseases was limited. I was unable to make a definite diagnosis of the case, so I prescribed for the urgent symptoms and said that I should call the following day. In the interval I went over again the literature of German measles and all skin eruptions with a temperature and concluded by forming a strong suspicion that this was a case of typhus fever. I had never to my knowledge, as a student or as a practitioner, seen a case of typhus fever, for, mainly owing to the brilliant work of Sir W. T. Gairdner while medical officer of health of the city, it has been in recent times a comparatively rare disease in Glasgow. On calling the next day I found the patient no better but still I could not definitely say that it was typhus fever. To call in a consultant was out of the question as the people were so poor that they could not pay for my second visit. Becoming alive to the fact that if it was a case of typhus fever then the sooner the patient was in hospital the better for herself and the community at large I sent to Dr. J. B. Russell, the then medical officer, a notification of typhus fever, with a note of interrogation after it to imply an indefinite diagnosis. He afterwards informed me that the case was typhus fever. The patient was promptly removed to the hospital while the other members of the household, two of whom, I believe, developed typhus fever, were removed to the reception house for contacts. There had not been a case of typhus fever in the city for months prior to it and there was no other case of typhus fever from the same locality for months after this. I was convinced at the time, and am still more convinced from what I have seen since, that if I had waited until I could have formed an exact diagnosis I should have had, not one, but several cases to notify, for the case occurred in a locality which has a density of something like 300 per acre.

The other instance became so famous that I confess to much diffidence in referring to it. It was the first to be recognised of the cases of bubonic plague in the outbreak here last year. These cases are fully reported in THE LANCET of Sept. 8th, 1900, p. 758, and the point I wish specially to emphasise, as bearing on the question under discussion, is that here again an indefinite and not a definite diagnosis was notified. When I examined these three cases in the same house, on my first and only visit, there was no difficulty in saying that whatever was the exact nature of the disease it was undoubtedly infectious. I determined to notify them at once as cases of enteric fever, with a query to indicate an incomplete diagnosis. I did so after calling on the medical man in attendance, who notified them at the same time in a similar manner. If we had delayed much longer for the purpose of forming an exact diagnosis what would have happened is obvious.

One word on the opposite side of the question. The other day I sent into the Ruchill Fever Hospital a baby of nine months notified as diphtheria (?). It was recovering from an attack of measles, when it suddenly developed that hoarseness and urgent suffocative breathing that so often indicate the beginning of laryngeal diphtheria. I was officially informed that the case was regarded as one of simple laryngitis, while the mother told me in angry tones that I had made a great mistake, for the child had no diphtheria, but the "dregs" of measles, and was put among the patients convalescing from that disease where it is at present. Now, what harm was done in this case? If I could have isolated

the child for a day or two with any degree of safety to others I would never have sent it away. But isolation was impossible in a house full of children as well as a block full of children, and I knew from previous experience that while waiting for the development of conclusive symptoms, and if it had been a case of laryngeal diphtheria, I should have more than one case to notify. The only harm done—and it was slight—was to my professional reputation, and even this might have been avoided if the mother had been simply told whether the child was better or worse and no opinion expressed on the diagnosis. The only other point is the notification fee. Personally I do not care a straw whether I am allowed it in this and similar cases. I could, however, claim it for the general practitioner solely on economic grounds, inasmuch as the majority of his suspicions will be confirmed and by thus limiting the spread of the disease he will considerably diminish the number to be treated in hospital at the public expense.

I am, Sirs, yours faithfully,

Glasgow, Oct. 21st, 1901.

THOMAS COLVIN.

## ROYAL MASONIC INSTITUTION FOR BOYS: CASE OF REGINALD E. A. WEBSTER.

To the Editors of THE LANCET.

SIRS,—May I be allowed on behalf of all interested in Reginald E. A. Webster's election to the Royal Masonic Institution for Boys to thank you and the many medical Masons who so kindly helped us? By your aid he was placed first on the list of 20 successful candidates with 7137 votes.

I am, Sirs, yours faithfully,

Queen Anne-street, W., Oct. 15th, 1901.

JOSEPH POLLARD.

## THE TOXIC ACTION OF BELLADONNA PLASTER.

To the Editors of THE LANCET.

SIRS,—In confirmation of your remarks on the above in an annotation in your issue of Oct. 19th, p. 1061, may I refer you to the following extract of my "Rough Notes on Remedies" which appeared in THE LANCET several years ago:—

"I may here remark that special caution ought to be observed in ordering or applying a belladonna plaster of large size. Anything over six, or even five, inches square is almost sure to produce some systemic effects, such as slight giddiness and uncertainty of gait and vision; and later, when the plaster produces pustular irritation, a fresh absorption of belladonna sometimes takes place, with a more decided occurrence of the above symptoms, and so susceptible are some that the mere application of a small belladonna plaster will produce the above effects with great violence."—I am, Sirs, yours faithfully,

WM. MURRAY, M.D. Durh., F.R.C.P. Lond.

Swinburne Castle, Northumberland, Oct. 19th, 1901.

## THE MORALS OF THE CONCIERGE.

To the Editors of THE LANCET.

SIRS,—I quite agree with what your Special Commissioner says about the *concierge*. I have considerable experience of him myself in Paris and he is a well-known character on the French stage. All the same I think the remarks hardly apply in this country where any system of espionage is not only unknown but abhorrent. I was very precise in defining the duties imposed on caretakers by the Workmen's Dwellings Company—viz., (1) to select tenants, satisfying themselves first, that they are of good character, and secondly, that the income of their household is low enough to justify their admission into the company's property; (2) to supervise the people generally, to prevent over-crowding and sub-letting, and to enforce order and quietness; (3) to prevent the improper use of the water-supply, water-closets, washing-houses, dust-shafts, &c.; (4) to enforce the cleansing of stairs, landings, balconies, courts, chimneys, &c.; (5) to report infectious disease to the authorities; and (6) to execute minor repairs.

I am satisfied that strict caretaking of all tenement houses on these lines would go a long way to get rid of the dirt and

disease which are looked upon as almost inseparable from so-called slum dwellings.

I am, Sirs, yours faithfully,  
D. M. STEVENSON.  
Glasgow, Oct. 21st, 1901.

## MALARIA AND MOSQUITOES.

*To the Editors of THE LANCET.*

SIRS,—In the early "eighties" I was practising on the Diamond Fields, South Africa, where malaria of the remittent type was very prevalent. At that time, I can safely say, there were no mosquitoes in camp. Our population numbered some 70,000. Some two or three years later, with the extension of the railway from Cape Town, came the first batch of these pests. But malaria, notwithstanding, steadily decreased both in my own practice (by no means a small one, as I was surgeon to various compounds in addition to being acting district surgeon) and elsewhere, generally speaking. I am a happy hunting-ground for all sorts of vampires—if I may here use the expression—and have endured martyrdom from bites. This week, whilst sitting on the front at Southend, I was bitten by a mosquito—I regret I was not sufficiently interested to preserve the specimen—and suffered worse than I ever remember, even abroad. I am surely saturated with mosquitoine (may I coin a word?) yet I am immune from neither malaria nor mosquitoes.

I am, Sirs, yours faithfully,

DAVID HARRIS,

Formerly Medical Officer of Health, Diamond Fields.

Imperial Service Club, Piccadilly, Oct. 9th, 1901.

## "THE AFTER-COMING HEAD; PREVENTION OF ASPHYXIA."

*To the Editors of THE LANCET.*

SIRS,—Dr. Blacker (THE LANCET, Oct. 19th, p. 1034) says: "..... It becomes a question whether it is not better practice to extract the head at once, even at the risk of a bad tear of the perineum, rather than to attempt to initiate the act of respiration while the head is still within the vagina." I should have thought cases must at times occur in which the tube method would provide just the few minutes' extra time required for proper relaxation of a rather tight outlet. I have often been surprised at the rapid relaxation which sometimes occurs during the four or five minutes preceding the birth of the head in a normal delivery, and this seems to me a reason why in a breech case a gain of a few minutes between the delivery of the trunk and of the head might sometimes be most useful. I should be grateful to Dr. Blacker, who points out that the method referred to is not approved—or even mentioned—by modern authorities, for further information on this point, and should like to know (1) if the tube method sometimes fails, and if so, why? (2) what are the objections to its use?

I am, Sirs, yours faithfully,

Upper Tooting, Oct. 22nd, 1901.

EDWIN SMITH.

## "THE HOME OFFICE ARBITRATION ON LEAD-POISONING."

*To the Editors of THE LANCET.*

SIRS,—I see from your annotation on this subject that you are under some misapprehension. You speak of the manufacturers and the workpeople as "one side" and "the other side" and imply that the Home Office is arbitrating between them, like the Board of Trade in industrial disputes. The case is entirely different. The arbitration is between the Home Office and the manufacturers *plus* the workmen, both of whom object to the proposed rules. It is quite right that the workmen should be represented and I hope they will be, equally with the manufacturers, but to speak of the two as "one side" and "the other side" is to mis-state the position. They are both, for different but not antagonistic reasons, on one side; the Home Office is the other.

I am, Sirs, yours faithfully,

Savile Club, W., Oct. 22nd, 1901.

A. SHADWELL, M.D.

## THE RECONSTITUTION OF THE ROYAL ARMY MEDICAL CORPS.

*To the Editors of THE LANCET.*

SIRS,—In THE LANCET of Oct. 5th, p. 929, you published the scheme for the reorganisation of the army medical services and in your leading article you stated the favourable impressions which you had received from your first perusal of the report of Mr. Brodrick's Committee, and expressed a lively sense of recognition of the earnest attempt which had been made to place the Army Medical Services upon a new and better footing. You regarded the report as the sketch of a scheme moulded on certain lines and admitting of a good deal of freedom of action in the way of such improvements and modifications as might hereafter be found necessary or advisable, pointing out that some of its recommendations must as regards their effect and working partake more or less of the nature of an experiment. I have now had time and opportunity to consider thoroughly the proposals, and while agreeing that this scheme is an earnest attempt to set the Royal Army Medical Corps on a basis of real excellence, yet I feel that carefully considered comments, even when adverse, can only be of service to the authorities. The proposals which I believe will not prove to be acceptable are partly the result of the composition of the Committee, which perhaps contained too much of the civilian element to enable it to understand correctly military medical problems, and are partly due to the complexity of the questions involved and the great practical difficulties which stand in the way. There is much that is good, indeed very good, in the proposals, but I believe that I am right in stating that certain modifications are absolutely necessary before a sufficient number of men will be attracted to the ranks of the Royal Army Medical Corps.

It is a fair arrangement that opportunities are to be given for suitable civilians over age who have served with troops in the field to enter the corps, and an excellent point that all candidates shall appear before an Advisory Board who will decide whether they may be allowed to compete for commissions. This appearance will give the required opportunity for the consideration of the social status of each candidate and of his fitness from this important point of view to hold a commission in His Majesty's army.

I have my doubts as to the "workability" of an Advisory Board with such extensive functions. Its number is, I think, too large for a working committee, and I fear that its observations and decisions may prove a cloak under which the sense of responsibility may in a great measure be lost by the Director-General. The pay of the civilian members has been fixed at too low a rate to prove an attraction to really good men; where an onerous duty to the State is required reward commensurate with the work and responsibility must be tendered. It must be remembered that an Advisory Board has been tried before and proved a conspicuous failure. It appears to me that the power and prestige of the Director-General will be diminished, though his pay is to be considerably increased. I am of opinion that his power should be retained and his usefulness be increased by appointing him to a seat on the Army Board, his opinion being limited to medical affairs, and that he should be given the real rank of a Lieutenant-General. The eleventh paragraph for the guidance of the Advisory Board is surely unnecessary, for it shows a want of confidence in the officers of the corps. It is, I think, a grave mistake to imagine that men of high training, military rank, and position will submit to a proposition that members of the Advisory Board may inspect the hospitals without notice of their intention. I am glad to see that it is proposed that the London examination shall be restricted to a clinical and practical examination in medicine and surgery, and that the subjects studied in the earlier days of the medical curriculum are not to be required from the selected candidates.

The scheme of sending lieutenants to Netley on probation for two months does not commend itself to me. I am surprised to see that the subjects of military surgery and tropical medicine are no longer apparently to form a part of the Netley curriculum, and I think that to cram the young lieutenants with bacteriology and hygiene for two months is a decided error; in two months little or nothing of these sciences can be usefully acquired, and I believe that the result will be the acquisition of an unpractical smattering of knowledge which will be only too readily forgotten.

The idea of allowing men holding resident appointments in recognised civil hospitals, or appointed thereto at such a date as will permit them to take up their duties immediately after they have passed the entrance examination for the Royal Army Medical Corps, is an excellent one, but I doubt the possibility of its practical application unless the numbers of the corps are to be largely increased. I remember hearing of one occasion when, at the commencement of a Netley session, the gentlemen who had held house appointments in civil hospitals were requested to stand up in the lecture theatre, the result being that nearly every man rose from his seat. With a regulation in force permitting men to enter the service before holding resident appointments I take it that the object of the candidates will be to enter as soon after qualifying as possible, and if the civil hospitals are willing to take them back for their house appointments but few men will be available in each batch to proceed to Netley and Aldershot for the appointed courses; but I rather doubt the willingness of the civil hospitals to give these posts to men who have already committed themselves to a career in which they can be of no future service to the consulting staffs of the various hospitals. I suggest that the period of a year passed as a house-surgeon or house-physician in a recognised hospital shall be allowed to count towards pension and promotion, whether the period were so spent before or after passing the entrance examination for the service. The time for which each lieutenant will be attached to a battalion is not specified, although a period of three years is implied. While considering this point a valuable one, as one destined to bring about a good feeling between the regimental and the military medical officer, I much doubt if any period of less than three years would suffice to do this.

The paragraphs which deal with the position of lieutenants after three years' service present an elaborate scheme which must have occupied considerable time in its preparation. I think it of importance that at the end of three years the services of an officer who has proved himself undesirable may be dispensed with, but what the opinion of candidates for the examination for commissions will be on this point is another question. In my experience youth is unconscious of its failings and shortcomings, but is little likely to place any confidence in such an unassured future. I altogether dissent from the proposition to accelerate promotion according to a scale of marks obtained at an examination: such a scheme is most difficult to carry out and must lead to envy, hatred, malice, and all uncharitableness. A far better plan, in my opinion, would be to give a graded pay at extra rates for the result of a practical examination, giving a separate rate of pay to men who reach the higher standards of efficiency and as far as possible employing them on special work, but allowing seniority to remain as it was in the corps. This criticism is equally applicable to the acceleration proposed as the result of the examination for the rank of major; I regard all such promotion as vicious and likely to bring about great dissatisfaction. On the other hand, to leave seniority as it was in each rank and to give extra pay to high-class specialists would be an excellent move and one which would meet a real want in the service as at present administered. The proposed sum of 2s. 6d. a day I regard as quite insufficient for this real need. I cannot imagine that officers will care to qualify as specialists to gain such an insignificant advantage. I regard the proposed examination before the completion of 20 years' service as an unnecessary evil. I maintain that to subject an officer of 45 years of age to such an ordeal is a ridiculous proposition and one which will keep candidates from coming forward for the public service. In no other learned profession is a man so examined for promotion to posts of responsibility—especially would it be wrong in a service like the Royal Army Medical Corps, for after men have been for years in India and other tropical countries where their physical and mental vigour is deteriorated it would be unfair to subject them to such examinations. If considered necessary, by all means let the promotion to the rank of lieutenant-colonel be by selection, but let this selection be a result of the qualifications shown by the officer as observed and reported on by the officers under whose command the 20 years of service have been completed.

I regard the touching of the pension of £1 a day after 20 years' service as one of the most serious mistakes proposed. Under this scheme the £1 a day cannot be counted

on, and hitherto it has been one of the greatest attractions to the service. This retiring allowance must be always conceded or I feel certain that candidates will not be forthcoming from the schools. It is quite unfair, I consider, to expect that men will run the risks of tropical service and permanent ill-health if their future is not secured to them—many men are more or less broken down by 20 years of service and a sum of £2500 cannot in any way be considered an adequate provision, for it will only produce an income of two figures. The eligibility of officers for brevet promotion is a good one, and I note with satisfaction that it is to be given for distinguished service of an exceptional nature as well as for distinguished service in the field. Charge pay of a hospital is also a welcome introduction. The arrangements for the treatment of patients under the principal medical officer in each army corps appear to me to be excellent, and I am glad to see that steps are to be taken to simplify the returns and the forms of accounts used in hospitals.

I consider the proposed rates of pay to be adequate to attract good men if some modifications are introduced in the conditions of service, but the pay of the colonel should be substantially added to. I do not think that £1200 a year would be too much to offer to this rank, and I would point out that on the proposed scale a colonel, if not in charge of a hospital, would actually draw less than a selected lieutenant-colonel holding such a charge.

The scheme put forward is of course a mere outline and I take it that it is published with the view of obtaining the opinion of the profession on all the questions involved. I would remark that in order to be of any real service to the State the Advisory Board must have more than a power to advise—there must be some guarantee that the advice tendered will be taken. I observe that nothing is said definitely as to the very necessary increase to the number of officers required for the corps. I believe that any number less than 1250 officers will not permit of the proposed study leave—which I regard as one of the most valuable recommendations of the Commission—if sufficient ordinary leave is to be permitted to the officers for rest and relaxation. The question of pay for the junior officers in India is but indefinitely touched on. The Indian Government, which has hitherto proved almost intractable, must be bound by a clearly-worded warrant as to the scale of Indian pay, which must include a proper rate of charge-pay for those officers who have the great responsibility of the charge of hospitals. I am glad to see that every army corps is to have a completely equipped bearer-company and field hospital and a proportion of other medical field units at its headquarters, for without such a provision it is impossible for the officers and men of the Royal Army Medical Corps to gain practical experience in the performance of field duties. I hope that a scheme which contains so much that is good will not be wrecked by the want of a real knowledge of the feelings of the profession, but I am fairly confident that the proposals, unless modified, will not bring forward either the kind or the number of competitors required.

I am, Sirs, yours faithfully,

Oct. 15th, 1901.

A WELL-INFORMED OBSERVER.

#### *To the Editors of THE LANCET.*

SIRS,—Your various correspondents seem to have confined their criticisms of the recommendations of organisation to the Advisory Board, the examinations, and such like things, whilst its pecuniary aspect appears to have been almost entirely passed over, it being taken for granted that a very substantial increase of pay is offered. I think, Sirs, I can show you that so far from this being the case the state of the corps will be much worse. For any man to enter the Royal Army Medical Corps merely for the sake of the annual pay would, of course, be absurd. The inducement lay in the pension, given after a certain number of years' (20) service. Was this not given no man in his senses, unless he was an utter failure, would think of joining. This inducement is now done away with, as after 18 years' service he can be compulsorily retired with a gratuity of only £2500. It is very true that the new scheme says that he is given his choice of remaining if he passes a certain examination, but we all know what this means. A word from the Treasury if economy was the order of the day and this choice would be

either withdrawn or the examination so screwed up as to be impassable, and out he would have to go *volens volens*. I speak of what I know when I say that the chance of any average man—unless he is blessed with influence in high places—being permitted to retire on a pension is not worth a button.

I have two sons on whose medical education I have spent about £2000. They have asked my advice and I tell them: "Infinitely better run your luck in private life than join a service from which you will be kicked out when too old to start life afresh and very likely with broken health."

I am, Sirs, yours faithfully,

Clifton, Oct. 22nd, 1901.

A FATHER.

P.S.—The following table shows the sum received during and after 20 years' service under the old and new scheme:—

Old Regulations.			Proposed New Ones.		
	£	s. d.		£	s. d.
5 years at £200 per annum	1000	0 0	3 years at £250 per annum	750	0 0
5 years at £250 per annum	1250	0 0	4 years at £287 per annum	1148	0 0
2 years at £273 15s. per annum	547	10 0	3 years at £307 per annum	921	0 0
3 years at £365 per annum	1095	0 0	2 years at £385 per annum	770	0 0
5 years at £410 12s. 6d. per annum	2053	2 6	3 years at £430 per annum	1290	0 0
	5945	12 6	3 years at £475 per annum	1425	0 0
Add pension of £1 per day, capitalised	5000	0 0		6304	0 0
	10,945	12 6	Add gratuity	2500	0 0
				8804	0 0

Or a difference of £2100 in favour of the present regulations. It will be noticed that the pay alone under the new scheme is £359, or just £20 per annum more.

## THE APPOINTMENT OF ASSISTANT MEDICAL OFFICER AT AN ASYLUM.

To the Editors of THE LANCET.

SIRS,—In a very few of the advertisements of vacancies for these appointments there is now being inserted a clause stipulating for annual re-election after service for a stated period of time. I should like to offer a word of caution to candidates applying under these conditions and to indicate, in the event of success, how such a clause may operate unfavourably and prejudicially. In appointments under the Metropolitan Asylums Board or in asylums where the governing body exercises a working control the danger that I fear may be non-existent, and the assistant medical officer may have a fair chance of his abilities and worth receiving recognition, but in an asylum where the medical superintendent is permitted to dictate and arrange the duties of every officer under him, and further to act as an impassable barrier between the committee and all subordinate servants of the institution, it is evident that the assistant medical officer must regard himself as totally dependent on the favours of the superintendent.

I have not personally experienced the effects of such a clause as I mention, but in the asylum in which I served for a number of years I can easily imagine the manner in which it may be used. The visiting committee never by any means became directly acquainted with the work of the officers and servants. Visitation of the wards and offices of the asylum was strictly confined to a 10 or 15 minutes' bi-monthly run (personally arranged and carefully conducted by the medical superintendent) through the male or female patients' divisions. Exceptional or occasional visits at unknown times or to entertainments, services, or special functions were never made. Not the slightest effort was ever made to ascertain or verify assigned reasons for removals or departures of members of the staff. The principles guiding the selection or appointment of subordinate officers, attendants, or nurses were beneath notice and practically every administrative and executive power was left with childlike trustfulness in the hands of the medical superintendent.

I must say in fairness that this condition of affairs had very little effect on me individually and the same may apply

to the prospective assistant medical officer to whom I address myself, yet I know of the grossest injustices having arisen from this state of affairs and of which the committee were kept in blissful ignorance. In such a case, it simply amounts to this, that the subordinate must first gain the personal favour of his senior officer. Given this he may succeed; but once forfeit or lose it and no amount of ability, devotion to duty, scientific work, or anything else will benefit him one jot or tittle. He is practically as dependent on the superintendent as if he were salaried and paid by him instead of by a public body that ought to have sense enough to perceive that *sometimes* it may even be for the institution's good that subordinate officers should have at least a modified measure of independence. Any attempt at this on the part of the assistant medical officer individually would simply result in his being crushed on the first favourable opportunity, and the committee—well, the committee would swallow, quite complacently, the bolus provided. Certain superintendents wish this opportunity to occur annually.

I am, Sirs, yours faithfully,

Oct. 22nd, 1901.

Ex-A. M. O.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*Great Increase of Plague Mortality.—Death-rates of Madras, Bombay, and Calcutta.—Training for Sanitary Officers in Bombay.—The Sanitary Shortcomings of Madras City.*

LAST week's returns merely showed a temporary suspension of the rise in plague mortality which has been going on for the past two months. This week there is a large and sudden increase from 5612 deaths to 7279. The Bombay districts return 6499 deaths, against 4844—chiefly in the Dharwar (1951), Belgaum (1290), and Satara districts—Bombay city 233, against 236; Mysore State 290, against 342; Bengal 99, against 72; Calcutta 16, against 13; Punjab 90, against 57; and the North-West Provinces 28, against 18. Benares district returned 18 deaths and Allahabad district 10. The widespread distribution of the disease is now very evident, and the increase in Bengal, the Punjab, and the North-West Provinces is very ominous.

The high death-rate of Madras has gone down, the last published figures giving it at 89 per 1000. The mortality, however, continues very high in some parts of the city. The death-rate in Bombay city is 58 per 1000, and that of Calcutta 25 per 1000. For the latter city there is a vast difference between the health of the urban area as compared with the suburbs. The latter has a death-rate of 38 per 1000, calculated on the old census figures, while the former is only 28 per 1000 by the same figures.

An important step in the direction of training sanitary officers has been taken in the Bombay Presidency. The idea is to train a class of sanitary engineers and health officers to take up posts in the Mofussil now filled by men with no special qualifications. The necessary instruction will be given at the Poona College of Science and practical work in the health and drainage departments of the Bombay municipality will be given by the health officer.

Bombay has got its improvement trust for the reconstruction and general improvement of the native parts of the city; Calcutta is waking up to its duties by dealing on an extensive scale with the remodelling of its insanitary bustees; and now it is high time that Madras should bestir itself and venture upon some general scheme of improvement. There are, for example, the dirty drains of Black Town to be got rid of. The health officer reports that "hardly any of the openings into the main drain of Black Town are trapped and the smell given off at various points from it is most offensive." Then there are the slaughter-houses—overcrowded, antiquated, and unprovided with many necessary arrangements. Again, there is little done to protect the public as regards its food supplies. The Health Department greatly wants strengthening in this direction, as immense quantities of bad meat, bad milk, and adulterated food-stuffs are sold practically without hindrance. The average death-rate of nearly 50 per 1000 is a strong indication that the sanitary requirements of the city have been neglected.

Oct. 5th.

## SANITATION AT EDINBURGH.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

So important an intellectual and educational centre as Edinburgh is in honour bound to keep well to the front in all matters relating to the preservation of public health. Yet this is no easy task. Like many other ancient and historical cities, Edinburgh was once surrounded by walls. The dwellings within these fortifications were consequently cramped for room and were therefore built to a great height and close together. Many houses abut only on to closes or narrow passages, and as they are built of stone and are six or more storeys high it would be a difficult and expensive matter to cut broad thoroughfares through these dense accumulations of inhabited and lofty structures. To make matters worse, it is in this, the oldest part of the town, that the poorest classes now live. As the town extended the prosperous sections of the community built for themselves more commodious houses and thus created what are now known as the New Town and the Southern Districts. This classification has facilitated the establishment of comparisons that are useful and incidentally bear on the question of the high death-rate in the South African concentration camps. Sir Henry Littlejohn, as medical officer of health, points out in a recent report the proportion of the population attacked by measles in the various districts. Taking the last three annual reports, the average cases of measles notified during the years 1898 to 1900 inclusive were equal to 39·8 per 1000 in the New Town; to 47·7 in the Old Town; and to 30·4 in the Southern Districts. The New Town, though better than the Old Town, is composed mainly of tenements, while the Southern Districts possess a large number of villas and self-contained houses. The figures are in accord with what might be expected—namely, that there were more cases in tenement dwellings and among the poorer sections of the community. Nevertheless, the difference is not so very great, and it is in the death-rate rather than in the number of cases that the effects of poverty and inferior sanitation are rendered manifest with startling emphasis. Thus the average annual death-rate was equal for the three years to 1·96 deaths per 100 cases of measles in the New Town, 4·26 in the Old Town, and 0·46 in the New Town. Here, then, we have a repetition on a small scale of the experience of the concentration camps in South Africa—namely, that the number of deaths from measles is not due to the number of the cases but to the want of proper nursing and accommodation for the patients. It would be difficult to find in Great Britain a clearer illustration of the effects of sanitation on the results of disease. The general zymotic death-rate in 1900, excluding diarrhoea, for the whole city was very low and amounted to only 0·96, but the deaths from these diseases were equal to 1·43 per 1000 of the population of the Old Town, to 0·90 per 1000 in the New Town, and to only 0·33 per 1000 in the Southern Districts and to 0·30 in Portobello.

At Edinburgh measles was included in the compulsory notification powers obtained by that city in 1879. After 20 years' experience Sir Henry Littlejohn has come to the conclusion that in the absence of proper means for isolation such notification has been of little service. It would be more useful, he considers, to notify erysipelas and puerperal fever, as these diseases might more readily be dealt with. As matters now stand the notification of measles is mainly of service in keeping the sanitary authorities better acquainted with the health conditions of the various localities and in indicating where precautions should be taken to prevent the spread of the disease in schools. Also, some of the more severe cases have been removed from the poorest houses to the hospital, thus giving the patients a better chance of recovery. But as the majority of cases cannot be removed to isolation hospitals there is no hope of stamping-out an epidemic of measles in the same manner as, for instance, an epidemic of small-pox.

Under these circumstances it is not surprising that the city has been anxious to increase its hospital accommodation for infectious diseases. For many years this question has been before the sanitary authorities, but the energy displayed in this cause was chiefly manifested during the prevalence of epidemics and generally died out when the

danger had passed. Yet so far back as 1497 the citizens of Edinburgh learnt to appreciate the usefulness of isolation. At that time there was a terrible epidemic of "grandgore," or French pox, and it was stamped out by deporting all the sick to the island of Inchkeith. Then, again, in 1513, after the battle of Flodden, there was a disastrous epidemic of bubonic plague. Wooden huts were erected on the Borough Muir for the isolation of the patients brought from Edinburgh. These huts were carefully burnt when the epidemic was over. The plague, however, broke out again in 1529, and then, for the first time, notification was enforced. The means of compulsion contrast forcibly with the small fines imposed in the present day; for anyone who failed to report a case of sickness was burnt on the cheek and banished from the city. Vagrants were closely watched, strangers entering the city were registered, and persons attending to the sick were threatened with pain of death if they associated with other people. Thus the principle that each citizen is responsible for his neighbour's health and life was fully established. Whether death was produced by the use of the assassin's knife or by the spreading of a fatal disease it was equally looked upon as murder; and in 1530 a man was hanged for going to church when his wife was suffering from plague and a woman was executed by drowning because, having the plague, she concealed the fact.

When yet another outbreak of plague occurred, in 1568-69, the authorities went a step farther. They not only isolated the sick but their families were removed to houses especially prepared for that purpose at the Muir and were there kept under observation, while their furniture was either burnt or thoroughly cleaned. This quarantine of "suspects" was maintained for 20 days. During the prevalence of plague in 1585 a system of scavenging was set up for the whole town, and the men who were employed were provided with a special uniform so that they should not soil their own clothes. This precaution has been revived in our day, and disinfectors generally wear overalls which are passed through the stove with the other objects that have to be purified. During the plague of 1645 the first approach to the appointment of a medical officer of health was made when Dr. John Paulit was engaged by the town and paid £80 (Scots) per month to attend to the cases of plague. This seems to have been the last stroke necessary to kill the foe; for from that time henceforth the plague has never reappeared in Edinburgh. It is a pity that the post of medical officer was not maintained after the cessation of this epidemic and only re-established 200 years later. Cases of leprosy were also strictly isolated and a gibbet was kept close to the lepers' house ready to hang those who came beyond the bounds in which they were confined. But in regard to the more ordinary forms of epidemic disease no such energy was shown; indeed, about 100 years ago Edinburgh was reputed to be one of the filthiest towns in the United Kingdom. Many well-known authors have denounced the revolting conditions in which even the more respectable inhabitants of Edinburgh were content to live. Nor was there any great improvement when the New Town was built, for the sanitary condition of the best new houses was most defective. One measure, however, was adopted—namely, the free vaccination of children—and this as far back as the year 1815. Some good was also accomplished by a big fire which destroyed many fever dens on the south side of the High-street, and a street-cleansing department was established by the corporation at about this time. The cesspools, the drains, and the sewers, however, were not touched, and when the cholera appeared in 1832 it spread most disastrously throughout Edinburgh. There were also many epidemics of typhus fever. On these occasions temporary sheds were erected for the patients in the grounds of the Royal Infirmary, but it was difficult to find anyone courageous enough to remove the patients from their houses to these sheds. It often happened that medical men had themselves to do this work and many of them lost their lives through contracting typhus fever from their patients.

It was in 1863 that the town council first appointed a medical officer of health and they selected the surgeon of the police, Dr. (now Sir Henry) Littlejohn, to fill that office. His first work was to make a sanitary survey of the city and to draw up health statistics for each district, thus demonstrating which were the worst and the most dangerous localities. This he supplemented by details as to density of population, air-space in the dwellings, cleanliness, &c. Then he denounced the condition of the drains, the bad sanitation of the better-class houses, the

frequent sale of diseased meat, the evil condition of the cemeteries, and many other obvious defects. This caused a great outcry, and it might have gone badly with Sir Henry Littlejohn if he had not been ably seconded by Dr. William Chambers who, most fortunately, was at that time Lord Provost. He later drew up an improvement scheme which is known as Dr. Chambers's Act, and new streets were opened out in the worst parts of the Old Town. Subsequently another leading sanitary reformer and medical man, Sir J. A. Russell, became Lord Provost, and in 1893 a second improvement scheme was passed. Meat-markets, dairies, bakeries, &c., are now inspected, and in all other respects Edinburgh is on a level with the best-administered towns of the kingdom. The result has been the saving of from 3000 to 4000 lives per annum. But the provision for the isolation of infectious cases was neglected till 1885, when the managers of the Royal Infirmary notified the town council that they could no longer provide for fever patients out of the funds of their charity. At this time the infirmary was about to remove to new hospital buildings at Lauriston, so the town council took over the old infirmary and converted it into a municipal fever hospital. Needless to say that this ancient structure is in no wise suited for the purpose and therefore considerable alterations had to be made. The fever hospital soon became quite popular and even wealthy citizens were glad to avail themselves of it rather than to keep fever cases in their private houses. An annual outlay of £4000 for the fever hospital had been allotted in 1885, but the expense had increased to four times that amount in 1893. It was then proposed to enlarge the fever hospital at the cost of £20,000; but the town council thought that they were spending quite enough money already and did not meet the proposal with favour. The very next year, however, the needed stimulant was provided in the shape of a small-pox epidemic. Huts had to be built for the patients in Queen's Park. They were an eyesore and a danger to the neighbourhood and a clamour arose. This served to educate and to ripen public opinion, so that now a magnificent fever hospital is in course of construction on a scale which seems quite regardless of expense.

Strange to say, however, that, in spite of the recent and wide extension of the city boundaries, the new isolation hospital is situated outside Edinburgh. It is stated that the House of Lords would not allow the site to be included within the city because the Lords wanted the county to make what profit it could from the outlay incurred by the town. The site consists of a farm of 130 acres on Colinton Mains. Forty acres were set aside for the hospital, which is to accommodate 600 patients; so there will be 15 patients to the acre, while at the old fever hospital there were 100 patients to the acre. All that appertains to the management of the hospital is situated in the centre; and on both sides, east and west, there are double rows of pavilion wards. All those on the east will be devoted to scarlet fever. To the north-west there are three pavilions, one each for diphtheria, typhoid fever, and erysipelas respectively; and on the south-west there are four pavilions for measles, chicken-pox, whooping-cough, and typhus fever. The reception and observation wards are near the principal entrance. Then there are an ambulance station, lecture-rooms, a pathological laboratory, a museum, and mortuary buildings; while in another part of the grounds there are the laundry, the boiler-house, the disinfecting station, the electrical power, and incinerator buildings. Ample open space remains for recreation-grounds. The amount of accommodation varies according to the diseases; thus there will be 10 beds for patients suffering from typhus fever and 329 for scarlet-fever patients. The cubic air-space for the scarlet-fever patients will amount to 2000 feet each, but for whooping-cough and chicken-pox the cubic space will be 1690 cubic feet per bed, the patients in these cases being nearly always little children. In the diphtheria wards 2545 cubic feet and in the typhoid fever wards 2514 cubic feet have been allowed, while in the case of typhus fever this has been increased to 3042 cubic feet for each patient. The pavilions run north to south with the ward offices to the north, so that the shadow of their greater bulk does not fall upon the wards, and they thus receive the maximum of sunshine. Each ward has two small separate rooms, one holding one bed and the other two beds, and of course there is a bath-room, and a duty-room, &c.

The ground is from 370 to 400 feet above the sea level and it dominates a gentle southern slope. It is well away from all buildings and the sun's light falls full on

the hospital without interruption. The spaces between the various pavilions will never be less than 80 feet, and as none of the blocks are more than two storeys high there cannot be any overshadowing. The stones employed are of a light-red colour and this gives a warmer appearance than the grey stone generally used at Edinburgh. In the wards great efforts have been made to introduce the most recent improvements. The floors are of solid teak planks, closely jointed, embedded in prepared pitch, and impregnated with paraffin wax. The walls are covered with Keene's or Parian cement and the angles are rounded off. Steam coils will be employed both for ventilating purposes and for heating, and, of course, by the windows that face each other a through draught can be established. The water-closets, the slop-sinks, the ventilated bed-pan cupboard, and the shoot for dirty linen, instead of being situated, as is generally the case, at the end of the ward, are built out from the centre of the ward; therefore it will not be necessary to pass before them in going in and out to see the patients. Electric light will be used throughout the buildings, and gas will be employed for ordinary cooking purposes. For drainage the separate system has been adopted. The roof and subsoil water will be discharged into the Braid Burn by a 20-inch pipe with a fall of 1 in 150. For the sewage the pipes are of heavy cast-iron, coated inside and outside with Smith's patent solution, laid on a gradient of 1 in 73, and they will measure nine inches in diameter. The lateral branches will be smaller and have a gradient of at least 1 in 40. Each pavilion has a separate connexion and ventilating trap, and there will be another ventilating shaft at the summit of each section of branch drains. All baths, sinks, &c., have disconnecting traps. The small-pox pavilion has a separate drain that goes straight to the outfall and does not mix with the rest of the system. Numerous automatic flush-tanks will be employed and a powerful disinfectant will be mixed with the water which they contain.

All the pavilions are connected with each other and with the administrative buildings by covered ways. Below these covered ways there is an underground passage where all pipes are laid and they are thus easily accessible. The nurses' home is a very large building four storeys high, with 130 separate bedrooms, some spare rooms, two sick-rooms, three day-rooms, a library, a recreation room large enough for concerts and other entertainments, and large outdoor recreation grounds. Then there is a separate block comprising the stores, the kitchen, the offices, and the dining-rooms. These latter are so divided as to separate the scarlet-fever nurses from the other nurses and they have different entrances. All the principal buildings are now completed as far as the masonry is concerned, but there is still an immense amount to be done within. The fittings, the flooring, the furnishing, and the gas, the water, the electric and other services will take a long time to put in. There is, indeed, much dispute as to when the hospital will be in a fit condition to receive patients. On visiting the hospital I found that some of the pavilions were much more advanced than the others, and the nurses' home is not so far from completion. Nevertheless, the works are not sufficiently advanced to venture upon any criticisms with regard, for instance, to the system of warming and ventilation. One thing, however, I did observe—that the principle enforced on the continent in schools, hospitals, &c., that heating should be provided near to the coldest surfaces, has been adopted here. Of course, the coldest surface is that of the window-panes. Therefore the hot-water coils are placed within the hollowed-out window sills. The heated air comes out of the top travelling up against the cold window-panes. This will prevent the down draughts that are created by cold surfaces, such as windows or marble walls, and which render it so difficult to secure the same temperature in every part of a ward, hall, theatre, or other large building. What the heating of such a hospital means may be gathered from the fact that there will be 3600 feet of hot-water pipes from the five boilers. These boilers measure 30 feet by seven feet each. These 3600 feet of pipes being all outside the wards in the underground passages, the figure does not include the pipes within the buildings. It is said that the hospital will cost nearly a quarter of a million of money; and this will certainly raise the question whether the same efficiency might not have been secured with a smaller outlay. In any case, when it is remembered that in 1893 the town council hesitated to spend £20,000 to enlarge the old fever hospital, the fact that they have now

incurred such an enormous liability shows that they have made great progress in the recognition of the principle that in matters relating to public health what appears to be economy is but the worst form of extravagance.

(To be continued.)

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### "Pearl Ash" Poisoning.

THE city coroner on Oct. 17th concluded the inquest on the body of a man named Brocklehurst, of Hayfield, who was said to have died from the effects of taking "pearl ash" instead of "potash." The deceased received a prescription from another man named Broadhurst who was, as many of the working classes are, somewhat of an amateur doctor, the terms of which were as follows:—"For sciatica or rheumatism: Take two table-spoonfuls of pearl ash to one pint of water. Boil and add the pearl ash, then let cool and bottle. Take one wineglassful night and morning." The druggist's assistant said that he did not remember serving pearl ash. "When asked for pearl ash he would dispense carbonate of potash," as the former had a strong caustic action. The son of the deceased, a boy, aged 12 years, said that his mother sent him for a pennyworth of pearl ash about two months ago, and he was served with "some dark-coloured substance like a stone." It is not clear how much of the solution was taken. After some time the man was removed to the Manchester Infirmary, where he was only able to take liquid food, and he gradually sank, dying on Oct. 9th. The coroner told the jury that "if a person totally ignorant of medicine took upon himself to administer dangerous remedies he was amenable to the law," and if they thought that the person who was alleged to have given the prescription had in giving it been guilty of "gross ignorance and scandalous inattention" they must send him for trial on the charge of manslaughter. The jury took a merciful view of the matter and were of opinion that the man who gave the prescription showed gross ignorance but not malicious intention, as he had acted in a kindly spirit. Their verdict was "that Brocklehurst had died from starvation caused by his taking an irritant poison prescribed by Broadhurst, who had been ignorant of its action." The coroner said that he thought the case ought to be investigated by the police and magistrates of Derbyshire. The inspector said that he would report it to his superior. This case is a good illustration of the ignorance as to the most ordinary things prevalent among our imperfectly educated people, and it is to be feared that little is done to disperse it by the present-day elementary teaching.

### The Leech Memorial Fund.

It is proposed in a short time to close the fund now being raised to found a memorial to the late Professor D. J. Leech. It now amounts to £1230, and the committee will be glad for any further contributions to be forwarded to the honorary secretary, Dr. E. M. Brockbank, 3, St. Peter's-square, Manchester.

### Manchester Schools for the Deaf and Dumb.

The committee of the Royal Schools for the Deaf and Dumb, Old Trafford, are appealing for increased support. It is now recognised that deaf children must receive a higher education than was formerly required "to enable them to compete in the labour market with persons not so afflicted," and thus the cost of their education has been increased. In 1881 there were 157 pupils and the cost per head was £20 11s. 9d. In 1891 there were 190 pupils at a cost of £27 2s. 7d. per head, and now, in 1901, there are 200 pupils and the cost per head has gone up to £34 19s. 5d. The school premises have had to be enlarged, and while 20 years ago there were about half-a-dozen teachers—some of whom were deaf—at small salaries, it seems that the educational needs require now 24 teachers, who, to comply with the demands of the Education Department and to teach efficiently on the oral system, must have had special training. The controversy as to the Blind Asylum still goes on, and the committee of the Deaf and Dumb Schools are anxious to let it be known that "the two institutions are in every respect distinct and separate, and that the two governing bodies have nothing in common beyond the spirit of philanthropy which guides their actions."

There is a debt to the bankers of £7754 on 'building extension account, to which must be added about £1123 for completing work now in hand. A small sanatorium for the isolation of sick children is much needed, but the committee are reluctant to build while they are burdened with their present debt. Assuming that the institution is managed financially with judgment and economy, a good case is made out for asking "the community of which Manchester is the centre" for increased help. The idea that these schools are affiliated with the Blind Asylum has no doubt arisen from the fact that "the two charities adjoin each other and are under one continuous roof."

### Scarlet Fever.

Scarlet fever has for some time been rather prevalent in Manchester, and in the Moss Side district the cases are very numerous. Dr. S. H. Owen, the medical officer of health, stated at the meeting of the district council that "he had reason to believe that scarlet fever patients had not been reported, either from great carelessness or ignorance of the infectious character of the disease." There is no doubt that in many mild cases no medical man is sent for and no notification is made.

Oct. 23rd.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### Intemperance and Insanitary Dwellings.

THE chairman of the Glamorganshire Quarter Sessions which were held at Swansea on Oct. 15th dwelt at some length upon the great increase in the number of indictable offences in the county. He said that drunkenness was on the increase to such an extent that unless something very drastic took place they would be having such a state of things that they would never be able to hold up their heads among the inhabitants of other counties not only of Wales but of England. No particular remedy was suggested, though the provision of rational forms of amusement was spoken of with favour. To those who live in the densely populated districts of South Wales there can be no doubt that the insanitary conditions of many of the working-class dwellings account to a large extent for the drinking propensities of the inhabitants. The responsibility for the existence of these conditions rests primarily with the sanitary authorities, but the Local Government Board, though aware, through the reports of the medical officers of health, of the state of most of the districts, has dealt very tenderly with the shortcomings of the authorities. One instance may be given. In the year 1895 Dr. R. Deane Sweeting reported to the Local Government Board upon the insanitary condition of the Amman valley district in Carmarthenshire, and made certain suggestions as to the improvements necessary, but when Dr. S. W. Wheaton visited the district in the spring of this year he found that little or nothing had been done in the direction of carrying out Dr. Sweeting's suggestions, and that there was still no proper system of drainage or of scavenging, that no means were taken to prevent the spread of infectious disease, and that there was no systematic inspection of the district for the discovery of nuisances.

### The Prevention of Consumption.

Upon the advice of the medical officer of health (Mr. E. Davies) the Health Committee of the Swansea Corporation has decided to invite the voluntary notification of phthisis from the medical practitioners in the town and to pay a fee of 2s. 6d. for each notification certificate received.—At the first meeting of the South Wales and Monmouthshire Branch of the National Association for the Prevention of Tuberculosis it was decided that the principle of subdivision should be adopted and that sub-branches should be formed. Circulars are to be sent by the committee to county and district councils emphasising the necessity for establishing sanatoria. Dr. C. T. Vachell expressed the opinion that an institution supported solely by voluntary contributions would not be likely to succeed.—The Bath Board of Guardians at a recent meeting discussed the treatment of consumptive pauper patients, and eventually decided to wait and see what the Bristol Board of Guardians would do in the matter of treatment of these cases. At the meeting of the guardians held on Oct. 16th the medical officer urged the guardians to act promptly and to provide proper accommodation for the treatment of phthisical cases.

The Bristol Guardians had suggested that the Bath Board of Guardians and themselves might jointly provide an institution for the treatment of these patients. Eventually it was decided to appoint a sub-committee to confer with the Bristol Guardians.

#### *Insanitary Dwellings in Cardiff.*

The two most prominent public health questions at the present time are the housing of the working-classes and the prevention of tuberculosis, and they are questions which admittedly have a very close connexion. Nearly all the speakers at the recent Cardiff conference on tuberculosis emphasised the importance of providing dwelling-houses with a sufficiency of air-space and sunlight and with absolute freedom from damp surroundings. It is a little disheartening, therefore, to find that when steps are taken by the Cardiff Corporation to improve the dwellings of the poor, not only, as might be expected, does opposition come from the property owners, but that these are supported in their opposition by members of the medical profession. In January last the medical officer of health (Dr. E. Walford) presented a report to the corporation upon the courts and unhealthy dwellings in the town, and although there are practically no slums in the borough he was able to refer specifically to 134 houses in various parts which he considered should be dealt with, not as insanitary areas under Part I. of the Housing of the Working Classes Act, 1890, but separately under Part II. of the Act. Proceedings were taken on Oct. 17th before the deputy stipendiary magistrate with respect to six houses which, according to Dr. Walford's report, were provided, in common with five adjacent houses, with only a single water-tap and with only two water-closets, each defective in construction and without any water-supply for flushing, and in which most of the rooms were dark and damp—those on the ground floor being paved with stone and being without back doors or back windows and without floor ventilation. The houses generally were described as being old, in a bad state of repair, and much shut in by high buildings surrounding them on all sides and obstructing light and ventilation. Dr. Walford asked that these houses should no longer be occupied. Three local medical practitioners stated that in their opinion they were not unfit for human habitation and that their occupation would not be dangerous to health. The deputy stipendiary, after asking Dr. Walford if he was aware that in Leeds almost all the cottage houses are built upon the "back-to-back" principle, remarked that Leeds was not an unhealthy town and he subsequently refused to make an order to close the houses in question. The danger which lies in a little knowledge is thus once more illustrated, for if the magistrate will pursue his inquiries a little further he will find that not only has Leeds a high death-rate from all causes, a high zymotic death-rate, and a high infantile mortality-rate, but he will also learn that it has been conclusively shown in other parts of Yorkshire by comparisons extending over a series of years that the death-rate among the occupants of "back-to-back" houses is considerably higher than among those who live in "through" houses, although the conditions of the two classes of dwellings as regards age, construction, class of occupant, sanitary conveniences, &c., are precisely similar. If the deputy stipendiary magistrate desires to raise the death-rate in Cardiff which last year was 16.5 per 1000, to that of Leeds which was 20.2 per 1000, he will continue to refuse the applications of the medical officer of health, but the responsibility must be his and not Dr. Walford's.

#### *Brentry Inebriates' Home.*

The Swansea Corporation has decided to contribute the sum of £1000 to the board of management of the Brentry Home, thereby securing a share in the management and seven beds for Swansea patients during the next 25 years. The chief constable has stated that there are now in Swansea 13 persons eligible for admission to the home. The corporation of Bath has entered into an agreement to secure three beds in the home during the next six years upon payment of £27 7s. 6d. annually.

#### *Employment of District Nurses by Sanitary Authorities.*

There is no provision for isolating cases of infectious disease in Ebbw Vale, a colliery district in Monmouthshire with a population of 21,000 persons. Owing to severe outbreaks of diphtheria and typhoid fever the district council recently engaged two district nurses, but the Local Government Board now state that there is no legal authority empowering the council to pay nurses for attending patients at their own homes.

#### *Hereford County Asylum.*

Extensive additions to the Hereford Asylum were formally opened on Oct. 15th. They consist of new quarters for the assistant medical officer and for the matron, a one-storey block to accommodate 50 male patients, and a two-storey block for 100 female patients. The dining-hall and the chapel have been enlarged and the laundry accommodation has been increased. The new buildings like the old are ventilated and warmed on the "Plenum" system. The cost of the extensions is about £40,000. The asylum was erected in the year 1871 on a site of 10 acres, with 100 acres of garden and farm lands, at a cost of £67,000, with accommodation for 187 men and 213 women. At the present time, therefore, 550 patients can be accommodated. The institution serves the city of Hereford and the county of Herefordshire with a total population of 114,000 persons.

#### *Plymouth Royal Eye Infirmary.*

This new building, although occupied by patients for the past 12 months, has not been formally opened, the ceremony being postponed owing to the death of Queen Victoria. It has now been arranged for the formal opening to be performed by the Countess of Morley on Oct. 30th. The cost of the institution, including furnishing, has been £12,000, and the committee make an urgent appeal to the public for more subscriptions.

Oct. 2nd.

### SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Death of Dr. Foulis of Edinburgh.*

By the death of Dr. James Foulis on Oct. 14th Edinburgh has lost one of its leading and most successful practitioners. He was a native of New South Wales, his father having been a medical man in Sydney. He was born in 1846 and he graduated at the University of Edinburgh in 1874. He was a thesis gold medalist of the University. He succeeded Dr. George Keith in practice and rapidly became a busy family practitioner. He took a keen interest in some biological questions and did important work on diseases of the ovary. Of late years he took a very active interest in the question of the transmission of infectious diseases by means of milk, and his voice and pen were used to enforce his views upon the profession and the public. He was a man of distinct intellectual capacity; he had the gift of ready and effective speech; he formed strong opinions which he did not fear to express, and he had a faculty of imitation which sometimes gave a humorous effect to some of his communications. He was altogether a unique personality in the profession in Edinburgh, and although he was neither a teacher nor a hospital physician no man in Edinburgh was looked upon with greater interest by his brethren, and his patients were devoted to him. He died of cardiac disease aggravated by an attack of influenza last spring.

#### *Direct Representation on the General Medical Council.*

Dr. W. Bruce of Dingwall intimated some time ago that he would seek re-election as the Direct Representative for Scotland on the General Medical Council. It has just been announced that he is to be opposed by Dr. Norman Walker of Edinburgh. It will be remembered that when Dr. Bruce was elected he won the seat over Dr. Sinclair of Dundee. The idea prevalent at that time was that no teacher need stand, as the general practitioners had decided to have one of their own body to represent them. It was thought that all persons connected with universities or corporations had the interests of those bodies more at heart than the interests of the general practitioners, and that the wrongs, either real or imaginary, of practitioners would have a better chance of being rectified by the voice of a general practitioner than of anyone else. I have no means of knowing whether the profession in Scotland is satisfied with its present representative, but a contest has at least the advantage of stirring up the stagnant pool of professional apathy. So far as Scotland is concerned it does not seem that there are any burning questions agitating the mind of the general practitioner at present, and he, of course, holds the voting power.

#### *General Council of the University of Edinburgh.*

The half-yearly meeting of this body is to be held on Friday, Oct. 25th. Motions dealing with the reorganisation of the medical curriculum and the time spent by professors in teaching their practical classes have been given notice of

and a report on the Carnegie Trust will be submitted. The meeting promises to be a lively one.

#### *Glasgow University.*

The winter session of this University was opened on Oct. 17th. Following the custom of recent years there was no formal introductory address, but several of the professors opened their respective classes with lectures on special subjects. Not unnaturally the Carnegie foundation and its probable influence upon education in Scotland came in for much acknowledgment and comment. It is, perhaps, noteworthy that one of the more recently appointed professors proclaimed his belief that the most urgent want of the Scottish universities was freedom from the compulsory ordinances enacted by the recently defunct Universities Commission.—The movement in favour of the better endowment of the University has been officially brought before the corporation, and it is reported that the Finance Committee has agreed to recommend the town council to make a grant of £5000 to the University fund. It is understood that if this is done the money will be "earmarked" to aid in the foundation of a lectureship in political or social philosophy.—The University Court will shortly appoint additional examiners in chemistry, zoology, materia medica and therapeutics, medicine and clinical medicine, and surgery and clinical surgery. The appointment in each case will be for three years from Jan. 1st, 1902, and applications must be lodged on or before Dec. 3rd next.

#### *Glasgow Extra-mural Schools.*

The winter session at Anderson's College Medical School was opened on Oct. 17th with an address by Dr. George A. Gibson of Edinburgh. In his introductory remarks Dr. Gibson spoke in commendation of the maintenance of freedom in teaching, which had led to the great development of medical education both in Edinburgh and in Glasgow. He recalled the fact that the medical school of Anderson's College had just completed the first 100 years of its existence and quoted the names of many famous men who had been students in the college. Afterwards he spoke on the importance of scientific study in medicine.—At St. Mungo's College the introductory address was delivered by Professor Malcolm Laurie who dealt with the position of the natural sciences in the medical curriculum. In so doing he criticised adversely the recent action of the English Colleges, which he condemned as reactionary and hurtful to the interests of medical education. The scientific subjects, he considered, could not be efficiently taught in schools, nor could the student do justice to them while occupied in studying for the preliminary examination. He insisted on the importance of an adequate scientific training in order that medicine might retain its position as a learned profession.—The increased interest in post-graduation study is manifested by the facilities which are now being offered to practitioners at several of the Glasgow medical schools. At the Eye Infirmary the surgeons are to give a joint course on refraction and the use of the ophthalmoscope. A similar series of demonstrations is announced at the Ophthalmic Institution, and at the Royal Infirmary classes in practical pathology and bacteriology are to be conducted. In all these cases the courses are free to qualified practitioners.

#### *Glasgow South-west Medical Society.*

The annual dinner of this society was held on Oct. 18th, under the presidency of Dr. John Stewart. There was a large attendance of members and guests, including Professor McCall Anderson, Dr. Bruce of Dingwall, Professor Stockman, and Professor Glaister. The toasts included "The General Medical Council," in proposing which Dr. Charles E. Robertson criticised adversely the refusal of the Council in June last to receive a deputation representing Scottish practitioners. In reply Dr. Bruce expressed the opinion that the Council is too large, and advocated a change in its constitution so as to make one-half of its members Direct Representatives of the profession.

#### *St. Andrews University.*

Dr. James Musgrave, at a meeting of the Senate on Oct. 16th, was formally introduced to the chair of anatomy recently founded by the late Marquis of Bute. The installation of Lord Balfour of Burleigh as Chancellor of the University is to take place on Oct. 24th. At the ceremony the degree of LL.D. is to be conferred on Lord Balfour, Sir Henry Craik, and Sir George Reid. Mr. Andrew Carnegie, LL.D., has in response to the students' invitation, intimated his willingness to stand as a candidate for the Lord Rectorship of the University.

Oct. 22nd.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Health of Belfast.*

At a meeting of the Public Health Committee of Belfast held on Oct. 17th, it was stated that the number of cases of typhoid fever notified during the week showed a considerable diminution. Apparently the epidemic has gradually worn itself out. In reference to the attempts to find out the causes of the occurrence of this fever in Belfast, in addition to inquiries made by the health department it has been decided to have bacteriological examinations of the soil made in certain cases, in order to prove or to disprove the allegations frequently put forward as to the filled-in ground on which some houses are built or the saturation of the soil by sewage from improperly constructed drains being responsible.

#### *Armagh Sewerage Scheme.*

The engineer of the new Armagh Sewerage Scheme has signed an undertaking prepared by the solicitor of the council agreeing to pay the council all money that they may pay for damages, costs, and expenses, in settlement of any actions, or of sums that they may be compelled to pay by order of the judges owing to flooding caused to certain houses, inasmuch as the engineer had "caused to be substituted an 18-inch pipe for a 24-inch pipe from the courthouse to the railway culvert contrary to the plans thereof and without authority from the urban council or Local Government Board, and failed to have constructed storm overflows as shown in the plans."

#### *North of Ireland Branch of the British Medical Association.*

The autumn meeting was held in the Museum, Belfast, on Oct. 17th. After the reading of the minutes and the Council's report Professor J. W. Byers, the outgoing president, delivered a short address thanking the members for the courtesy and kindness shown by them to him during his year of office and introducing his successor, Dr. J. S. Darling of Lurgan. On the new president taking the chair, on the motion of Mr. G. L. St. George (Lisburn), seconded by Dr. J. C. Martin (Portrush), a very hearty vote of thanks was given to Professor Byers for his management of the affairs of the branch during the past year. The new president then delivered his inaugural address on the Danger of Delay in Operation in Surgical Affections, for which he was cordially thanked. Mr. T. H. Brownrigg (Moira) then read a paper on Notes of a Case of Typhoid Fever with Hyperpyrexia and of a case of Non-febrile Typhoid Fever. In the discussion which followed Dr. Martin, Professor J. A. Lindsay, Dr. J. Robb, Professor Byers, Dr. W. Calwell, and the President took part. In the absence through illness of Dr. J. C. Rankin the secretary read a paper by him on Four Cases of Enlarged Spleen. A discussion followed.

#### *Remuneration of Locum-tenents of Dispensary Medical Officers by Boards of Guardians.*

The question of the remuneration of substitutes for dispensary medical officers has again arisen. It would appear that the Ballymoney Guardians had fixed the scale of remuneration for locum tenents at two guineas per week. Dr. J. Wallace refused to accept this sum, stating that he could not procure a substitute at such a figure. Subsequently Dr. Wallace being temporarily unable to work owing to sickness, notified the relieving officer, and he appointed Dr. M. J. O'Kane of Ballymoney as substitute, who claims six guineas for the two weeks' work. The guardians have requested the Local Government Board to hold an inquiry into the whole matter.

#### *Deaths of Medical Men.*

On Oct. 16th a well-known and respected Ulster practitioner, Dr. R. B. McClelland, died from apoplexy at his residence, Banbridge, co. Down. Dr. McClelland, who was the son of a medical man, graduated M.D. of Glasgow in 1849. He practised all his life at Banbridge, where he was much respected. He was a J.P. of co. Down. His funeral, which was largely attended, took place on Oct. 19th. On Oct. 18th Dr. Hugh Fisher, one of the younger Belfast medical men, died from heart failure after a severe attack of typhoid fever. He was only 31 years of age. He studied at Queen's College and graduated in 1893 in the Royal University of Ireland. Dr. Fisher was greatly respected by his fellow practitioners and by his patients. He married Dr. Elizabeth G. Bell, and she and an only son, two years of age, survive to deplore his early decease.

*The Medical Profession and University Education in Ireland.*

The President of Queen's College, Galway, has written a letter to the press, in which he says that Dr. W. A. McKeown asserts<sup>1</sup> that Galway College has had only 16 medical graduates in 10 years. The President states that the number of medical graduates in the Royal University alone in 10 years (1891-1900) was 42. In addition to these five other students obtained further medical qualifications in the same university. Dr. McKeown, in reply, says that the number 16 represents the total number of students educated at Galway College alone for the final examination in medicine in the Royal University. The mistake as between 16 and 42 has arisen, Dr. McKeown thinks, because the President must have counted students who have passed their early medical studies in Galway College, but who have gone to other colleges for their final studies, as if they remained all the time at Galway. It is the difficulty in the study of the clinical side of medicine, surgery, &c., which causes students of the medical faculty to leave Galway in the later years of their curriculum.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Hospital Medical Officers and the New Law concerning Accidents.*

I HAVE on previous occasions referred to the new law concerning accidents to workmen sustained in the course of their occupation. This law provides that employers shall be responsible for all medical care and for drugs supplied to any workman who has met with an injury in the course of his work. Both ordinary general practitioners and hospital physicians and surgeons protested against this law. Employers naturally pay less than if the workman were treated at home, and also with a view to his getting the best treatment they send him off to the nearest hospital. In this manner the general practitioner is deprived of many fees which would have fallen to his lot and hospital physicians and surgeons lose also, for they have to treat gratuitously many people whose cases would have been a source of profit, for the bill would have been discharged by the employer. A medical man at Clermont-Ferrand, by name Dr. Bousquet, has taken the initiative and has summoned his colleagues to a meeting to be held on the eve of the Congress of Surgery for the purpose of considering what measures can be taken to lay before the congress the just demands of medical men.

*Methods for the Suppression of Small-pox Inoculation.*

At the meeting of the Academy of Medicine held on Oct. 8th M. Hervieux read a paper upon Small-pox Inoculation and Native Inoculators. Despite the incessant efforts of military surgeons and colonial medical officers small-pox yearly claims a certain number of victims in the colonies, being brought about and spread by the practice of inoculation. In M. Hervieux's opinion the best way of combating this evil is to try to raise up a race of native vaccinators and so to convert the natives to a belief in vaccination. This opinion, said M. Hervieux, is held very strongly by Dr. Le Gros, colonial medical officer of Kabylia. Not only would this plan provide for a great increase in the number of orthodox vaccinators, who are far too few in the countries specially concerned, but it would also get over religious scruples, for the vaccinator would be of a like faith with the vaccinated. M. Hervieux referred to other plans which have been put forward, but the one which I have mentioned seemed to him to be the most efficacious.

*Suicide in France.*

The number of suicides for the year 1898 showed a slight increase—namely 9438, as against 9356 in 1897, or an increase of 82. The figures for a period of five years before and including 1898 were as follows:—1894, 9703; 1895, 9263; 1896, 9260; 1897, 9356; and 1898, 9438. It seems fair to conclude from these figures that the diminution which began in 1895 was the commencement of a real diminution and not merely of a temporary one. The department of the Seine supplied one-sixth of the total number of suicides in 1898—namely 1566, or 64 less than in 1897. Of the persons committing suicide 85 were under 16 years of age, 477 were between 16 and 21 years of age, 1436

were between 21 and 30 years of age, 1285 were between 30 and 40 years of age, 1669 were between 40 and 50 years of age, 1852 were between 50 and 60 years of age, 2356 were more than 60 years of age and the ages of 278 were unknown. The civil condition of those committing suicide was ascertained only in 8899 cases. The unmarried numbered 3008, the married with children 2502, the married without children 1422, widows with children 1113, and widows without children 834. As to employment, 2436 cases occurred among agriculturists, 1668 among those employed in various industries, 1262 among business men and merchants, 1380 among those carrying on a profession, 1511 among domestic servants, and 1181 among those not in employment or whose employment could not be ascertained. As to motive, 1537 suicides were set down to poverty and reverses of fortune, 943 to family troubles, 624 to love or jealousy, 1226 to drink, 2705 to various troubles (of which physical pain accounted for 1785), 1347 to cerebral disease, and in 1056 cases the cause remained unknown.

*High Frequency Currents in the Treatment of Anal and Vulvar Pruritus.*

At the meeting of the Therapeutical Society held on Oct. 9th M. Leredde reminded the society that physical agents, like other methods of treatment, had their limitations from a therapeutical point of view. M. Leredde had especially remarked this in using high frequency currents for pruritus. If, however, this method were used for the treatment of pruritus limited to the anus and vulva excellent results might be obtained. He cited the cases of four patients suffering from anal or vulvar pruritus and in whom the disease had lasted from three to 12 years and had resisted all ordinary methods of treatment. One patient had suffered also from general pruritus which had yielded to dietetic treatment but the anal pruritus had persisted. After from six to 13 sittings, which took place two or three times a week and the duration of which eventually lasted for 15 minutes, all the patients were completely cured.

*The French Congress of Surgery.*

On Oct. 21st the Fourteenth Congress of the French Surgical Association was held in the large theatre of the Academy of Medicine. M. Lucas-Championnière was in the chair and was supported by Professor Jacques Reverdin of Geneva as vice-president, and by Dr. Brouardel (dean of the Faculty of Medicine), Dr. Bouchard, Dr. Guyon, Dr. Dieu (chief of the Army Medical Department), and Dr. Auffret (chief of the Naval Medical Service). In his opening address the President discoursed upon recent improvements in surgery and warmly eulogised the practice of antiseptics in which he firmly believed, despite the statements of the modern champions of asepsis, so that he frankly owned that he would like to see a return to the original doctrine of Lister. Dr. Guinard, the joint general secretary, who spoke in place of Dr. Picqué, gave a welcome to the foreign guests, of whom there were many, and the proceedings commenced by a discussion upon the surgery of the spleen. In the evening the President entertained some 200 members of the Congress at dinner.

ROME.

(FROM OUR OWN CORRESPONDENT.)

*The Granting of Degrees to Foreign Graduates by the Italian Universities.*

FOREIGN practitioners resident in Italy who are rendered uneasy by the repeated attempts lately made to restrict the privileges accorded to them by the present laws must all have felt a sense of their helplessness in face of the difficulty in which they would have found themselves had these attempts proved successful. Perhaps the British medical men have less to fear from this source than have those of any other nationality, seeing that the danger to them has been, in part at least, met by the application of Part II. of the Medical Act of Great Britain to Italy and the consequent removal of the bar which previously existed to reciprocity of medical practice between the respective countries. But in the case of American, German, Austrian, Swiss, and other foreign medical men a similar expedient is not available since none of these countries are prepared to act towards Italy in this matter with the liberality shown by Great Britain. It is natural therefore that these men, even more than their British colleagues, should look wistfully for some means of

<sup>1</sup> THE LANCET, Oct. 12th, 1901, p. 1012.

escape from the dilemma in which they would certainly be placed in case of any legislative changes of the kind recently contemplated. Such a means does in fact exist, although as yet it has not been taken advantage of to any extent. I refer, of course, to the obtaining of an Italian degree in medicine, which places its holder in a position of security from which no possible changes of the law can dislodge him. In almost every other country it is now impossible, without a prolonged course of study and the passing of many examinations, for a foreign graduate to obtain the diploma in medicine of any university of repute. But in Italy the case is quite different, for in virtue of old-time regulations made for circumstances now entirely changed the law not only permits, but obliges, the various universities to admit to the examination of "laurea"—which corresponds to the final examination for the M.D. degree of certain British universities—any medical graduate of a foreign university whose degree may be considered by the Superior Council of Education as equal in value to that of the Italian university whose "laurea" he is desirous of obtaining. Such foreign graduate is thus absolved from the passing of entrance and of all the other professional examinations, and all that is further required of him is the payment of the fees for the complete curriculum, amounting for the six years of medical study to about 900 lire (£36). For this modest sum, and by passing an examination by no means difficult to one conversant with the language, the "laurea" of any of the Italian universities may be obtained by an approved candidate. A short account of how this is accomplished at, for example, the University of Rome may prove of interest. The description, with slight modifications, applies to the method followed at all the medical schools of Italy in the granting of degrees to foreign graduates. Having sent his application, accompanied by his foreign diploma, to the rector of the university, and these having been laid before the Superior Council and approved of,<sup>1</sup> the candidate is informed that he may present himself for the examination of the "laurea" on payment of the fees already referred to. The latter condition having been duly complied with, and the candidate having put in a written request stating his desire to appear, a date is fixed, corresponding usually to the dates arranged for the "laurea" examinations generally, which it is customary to hold twice a year—namely, in July and in November. A fortnight before the examination he must lodge with the secretary of the university a written thesis of his own composition<sup>2</sup> on any subject he may choose from the whole range of medical study. At the same time he gives the title of two other theses which he is prepared to defend orally. One of the latter should bear upon surgery, but with this limitation the choice of subject in these also is equally unrestricted. The examination itself is conducted orally in Italian by a specially nominated Commission consisting of a president, five university professors, and five "liberi docente," in all not less than 11 members. To one of these, termed the "Relatore," selected for his special knowledge of the subject dealt with in the written thesis, the perusal of the latter has previously been entrusted, and it is his duty before the candidate is introduced to explain to his colleagues its scope and to state the opinion he may have formed of its merits. When the candidate appears before the Commission the Relatore and any other members who may so desire bring forward objections to the facts or theories contained in the thesis in such a manner as to give him an opportunity of defending them or of explaining them more fully. They may also put questions serving to elicit the candidate's knowledge on matters naturally arising out of the subject in hand. For example, if the thesis deals with a morbid condition of some particular organ he may be called upon to give some account of the development, the anatomical structure, or the physiology of the organ. A wide field is thus opened up for discussion, however limited the question may be to which the candidate has confined himself in his dissertation. The oral theses are next dealt with in a similar manner though not at such length, the

examination occupying altogether about one hour. The candidate is then asked to retire until the Commission has considered whether he should be accepted or rejected. Their decision is arrived at by voting, each member disposing of 10 votes, any or all of which he gives to the candidate according to the manner in which in his opinion the latter has acquitted himself. With 11 members on the Commission the maximum number obtainable is thus 110, but 66 suffice for a pass. The counting of the votes having been completed, the candidate is recalled, the result is announced to him, and if he has secured the requisite number of marks the degree is conferred upon him forthwith by the President. Very few British practitioners have so far availed themselves of the facilities thus offered to foreign graduates of obtaining an Italian diploma, some being deterred by their unfamiliarity with the language, others by a prevalent impression that they would not receive fair play from the examiners who are supposed to be very jealous of admitting foreigners to their degrees. This latter idea is not borne out by the experience of one of the English medical men practising in Rome who took the "laurea" of that University a few months ago. On the contrary he was treated with the utmost courtesy and not one unfair question was put to him from first to last. His examination, though long and somewhat trying on account of his imperfect acquaintance with Italian, was, he says, absolutely straightforward, and the result proved that if any partiality was shown it was in his favour since he obtained the degree with the full complement of 110 votes. While thus loyally carrying out the law as it stands at present, the Italian universities nevertheless begin to protest against a system which grants to foreigners on such comparatively easy terms privileges which native graduates only obtain at the expense of much time and study. If foreign universities returned the compliment they would not complain, but this is not so. The University of Pisa, for instance, recently addressed an appeal to the Ordini dei Medici calling for combined action for a repeal of this law, illustrating its unfairness by the case of a Swiss practitioner who had last year obtained the "laurea" of Pisa in the manner just described, although the university (Berne) at which he had taken his foreign degree offers absolutely no facilities to Italian graduates who may wish to take a Swiss diploma. Such a galling inequality is not likely to be permitted to continue, and foreign graduates ambitious of possessing an Italian degree would therefore do wisely to take it while they can.

Oct. 21st.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

### *Vital Statistics of Toronto.*

DURING the month of September there were registered at the office of the City Clerk of Toronto 339 births, 229 marriages, and 252 deaths. For the corresponding month of 1900 the numbers were: births, 328; marriages, 187; deaths, 290. The registration of births should be larger, as there are yet many physicians throughout the city who are careless with regard to registration, and if the parents also neglect to carry out the regulations with regard to it, it entails a diminished report. The city authorities may consider it again advisable to bring the delinquents before the police magistrate, as was done last winter.

### *Royalty at McGill University.*

During the visit of their Royal Highnesses the Duke and Duchess of Cornwall and York while they were touring to Montreal a visit was paid to McGill University, where the Duke performed the ceremony of declaring open the new buildings erected during the summer term for the requirements of the Medical Faculty. The address of welcome was presented by the Dean (Dr. Craik), who referred to the growth of this famous institution since it was organised in the year 1824. At that time four professors looked after the welfare of 25 students. In 1829 the Montreal Medical College was incorporated with McGill University, then having only 30 students. Last year was the most successful year in the history of the Medical Faculty, there being over 490 students on the rolls. It now takes 70 odd teachers and professors to attend to the medical education of this great number of students. His Royal Highness was presented with a small casket containing a gold key to the door of the new buildings which have been made possible through the generosity of two members of the family of

<sup>1</sup> Some of the Italian schools are not satisfied with this, but insist on the candidate producing certificates to show that he has been separately examined in, and has successfully passed at his own university, all the subjects (including, for instance, ophthalmology and dermatology) prescribed in the previous professional examinations from which he desires to be exonerated. Should the applicant be unable to furnish such certificates he is required to pass in each of the missing subjects before being admitted to the examination of the "laurea."

<sup>2</sup> If not actually written in Italian originally a translation of the thesis into that language must be supplied by the candidate.

Lord Strathcona—Lady Strathcona and the Honourable Mrs. Howard.

#### *Tuberculosis.*

Dr. J. George Adami, professor of pathology at McGill University and superintendent of the Dominion Pathological Laboratory, calls attention to the fact that Professor Koch's recent announcement at the British Congress on Tuberculosis is not by any means a new idea in Canada. Two years ago when the Canadian Medical Association met at Toronto, Dr. Adami contributed a paper with the title, "Is Bovine Tuberculosis Infectious from Animal to Man?" in which he maintained that this was very doubtful.

#### *Ontario Provincial Board of Health.*

The nineteenth annual report of the Ontario Board of Health has but recently been issued and gives some interesting information regarding the health of the province for the year 1900. It shows that there were 25,383 deaths reported in that year, or an average of 11.9 per 1000. The deaths from contagious diseases are given as follows: Scarlet fever, 133; diphtheria, 486; measles, 93; whooping-cough, 121; typhoid fever, 550; consumption, 2360. Consumption by months was as follows: 183, 186, 188, 203, 239, 290, 264, 180, 172, 169, 161, 215. From these returns it would appear that the death-rate from consumption in Ontario could be set down at 10 per cent. There were 161 cases of small-pox with 13 deaths. A very noteworthy decline is seen in the deaths from diphtheria during the past nine years in this province—in 1887 there were 1786 deaths; in 1893, 1044; in 1894, 1075; in 1895, 942; in 1896, 925; in 1897, 976; in 1898, 634; in 1899, 599; and in 1900, 480. The work done in the laboratory embraced an examination of 1669 specimens.

#### *Re-opening of the Medical Schools.*

The medical mills are all at work again grinding out new recruits for the ranks of medicine. In several of the principal colleges there have been great improvements made in laboratories, new buildings have been erected at considerable expense, and great preparations have been made to handle the increased influx of students. Nearly all of the colleges are claiming largely increased first-year classes; and it would appear that more young men are entering upon the study of medicine than at any other time in the history of medical education in this country. As examples of this great prosperity for the medical schools Toronto, Trinity, and McGill may be cited. Toronto has been steadily gaining ground; she has within the last three years outstripped her rival Trinity, and seems to be rapidly forging ahead of the great McGill. The number of new students at Toronto has doubled within the last four years. In 1897-8 61 students registered in the first year; in the following year there were 73; two years ago there were 104; last year there were 124; and for the present year the Dean (Dr. Reeve) is the authority for the statement that before even a single lecture was delivered a larger number of students had been enrolled than were ever enrolled before. Trinity, too, is not far behind, more students being registered on the opening day than had been registered at the same time within 20 years. What this large influx into the ranks of the medical students portends for the profession of medicine when the recent census announcement has been so disheartening will certainly form a very interesting study in the immediate future. Queen's at Kingston, in the eastern part of Ontario, seems also to be well to the fore, but if recent words of the Rev. George M. Grant, principal of that University (who is now lying seriously ill) carry any weight, Queen's is going to make a determined effort to weed out, in the English as well as in the professional branches, irreverent and under-taught students who do not take the study and the subsequent practice of their profession seriously.

#### *Toronto Clinical Society.*

The first regular meeting of this society was held on the evening of Oct. 2nd, the President, Dr. J. F. W. Ross, being in the chair. Dr. H. A. Bruce showed a specimen of a Hairy Tumour which he had extracted from the stomach of a young married woman, aged 26 years—a specimen which he also showed at the recent meeting of the Canadian Medical Association. Dr. A. A. Small presented two patients: the first was a woman of 40 years of age with a Cystic Tumour of the Right Popliteal Space which was probably growing from a tendon-sheath or from one of the bursæ; the second case was presented by Dr. Small as a case of Polymastia. The so-called supernumerary breast was situated on the back of a

woman of 60 years who had borne several children. It was in appearance quite characteristic of a female breast, and its exact location was just behind the posterior axillary line of the right side, corresponding to the lower portion of the scapula. The small, nipple-like tumour had always been present, but the larger tumour upon which it was set had only developed within the last five years. Close inspection could not demonstrate any ducts opening on to the surface of the smaller tumour. The breast never underwent any changes when lactation was present. The general opinion was that the tumour was a lipoma, but it certainly looked very much like an ordinary female breast. Dr. A. A. Macdonald showed a specimen of a Cystic Adenoma of the Breast. He believed in removing the entire breast in these cases. An interesting point in this specimen was that eight weeks before operation no tumour could be demonstrated, although pain was a persistent symptom.

#### *Toronto Medical Society.*

This society opened for the winter session of 1901-1902 on the evening of Oct. 3rd, with Dr. F. N. G. Starr, the newly elected president, in the chair. Dr. Starr delivered a very interesting address on the deceased members of prominence and distinction in the profession from the days when Toronto was known as the "muddy town of York" down to the present time. The lecture, which was illustrated with the photographs of these fathers of medicine in this city thrown upon the canvas, was much appreciated by the members of the society. Mr. Irving H. Cameron showed a number of Calculi, 14 small ones of the collection having been extracted from the cul-de-sac behind the prostate in the bladder of an old gentleman, aged 76 years; the operation was by high section. Dr. Graham Chambers presented a patient, a girl, aged 13 years, who ever since three years of age had been troubled with Hydroa Vaccini-forme. Several scars could be defined upon the patient. Under full doses of arsenic she was now clearer of lesions than she had been at any time since the trouble began. Dr. Alexander Primrose and Dr. Graham Chambers presented a young man, aged 25 years, who came to Dr. Primrose with several warty outgrowths on different portions of his body. One appeared on the right malar bone, another on the right shoulder, another on the neck, and still another at the inner canthus of the right eye, simulating an epithelioma. Dr. Chambers diagnosed the condition as blastomycosis which was subsequently confirmed by finding the fungus under the microscope. Dr. Primrose operated by excising portions of the growths and applying the actual cautery. Two lantern-slide presentations on the canvas showed how much these lesions had improved. The patient took 80 grains of iodide of potassium three times a day for a period of six weeks.

Oct. 5th.

## **Obituary.**

ROBERT HEPBURN, L.D.S.R.C.S. ENG.

At the advanced age of 92 years Mr. Robert Hepburn died at his residence, No. 9, Portland-place, London, on Oct. 17th. Although full of years, and although his youth and middle age were passed amongst a generation that has gone by, his interest in life remained with him to the end, and he took his full share in social and philanthropic work until almost the last days of his existence. Robert Hepburn was born in Edinburgh, at Croft-an-righ, on Jan. 1st, 1810. He was educated at the High School of Edinburgh and in his early youth became apprenticed to a dentist. He left Edinburgh and came to London when he was 21 years of age and in London he lived and worked all his life. His profession brought him success and fortune whilst he practised in Davies-street, Berkeley-square, and later at 9, Portland-place. One of the pioneers in establishing dentistry on a scientific basis he was one of the very first to take the dental diploma at the Royal College of Surgeons of England when that corporation began to issue diplomas in dentistry. In 1859 Mr. Hepburn took a prominent part in founding the Dental Hospital of London, and it must have been very gratifying to him to know that the institution he fostered so carefully is at the request of the King, who has graciously consented to become the patron, to be styled in future the Royal Dental Hospital of London.

Mr. Robert Hepburn had long been known in professional dental circles as a wise and zealous reformer, for we read in a paper which was read by Mr. Alfred Hill in 1856 that "throughout the entire effort to raise the status of the dental profession and among its truest workers and supporters there has been no more candid worker and no more sincere and interested coadjutor than Mr. Hepburn." This honest endeavour to raise the position of the dental profession to a better status than he found it in was the keynote of his professional life and in this good work he had abundant evidence of success. Professional honours were Mr. Hepburn's in plenty. He was surgeon to the Dental Hospital of London; he was an early member, and afterwards president in 1870, of the Odontological Society of Great Britain; and at the London School of Dental Surgery Mr. Hepburn held the lectureship on Mechanical Dentistry for many years. By his colleagues Mr. Hepburn was highly respected for his professional ability and for his loyal exertions in their behalf at all times.

When we turn to his social life we find a theme which it is indeed difficult to do justice to. His professional work we can in some degree estimate; the positions he attained in learned societies have been held with distinction by other men; but Mr. Hepburn's social qualities can only be estimated by those who came in contact with him and who came under the magic of his personality. It was, perhaps, chiefly in Scottish circles in London that he was best known, but in every sphere of life his courtesy was recognised, his large-heartedness was appreciated, and the charm of his overflowing geniality commanded friends everywhere. Of fine physique—he stood six feet three inches and was proportionately broad and deep-chested—he has left few physical equals or physical superiors in the realm. His mental and social qualities were modelled upon his physical, and gave us a picture of strength, manliness, and amiability of character. These qualities were excellently portrayed by Sir Daniel McNece, President of the Royal Scottish Academy, in his painting of Mr. Hepburn. In 1857, when the picture was painted, Mr. Hepburn was in his prime, and never had painter a more handsome model to delineate. The portrait was presented by the members of the Caledonian Society of London, a society of which Mr. Hepburn was at once the founder and father. Eleven times was Mr. Hepburn elected president of this society, and by his constant endeavour, the urbanity of his manner, and his ever open-handed charity he played the chief part in carrying the society to a flourishing state. In every Scottish charity in London he played a part. The authorities of the Royal Caledonian Asylum recognised the work he did in behalf of that institution by the presentation of an illuminated address. He was a loyal supporter and a vice-president of the Royal Scottish Corporation, and it was at a meeting of this corporation that he made his last public appearance, when on Jan. 31st, 1900, he seconded a motion made by Lord Rosebery conveying a message of condolence on the death of Queen Victoria from the Royal Scottish Corporation. In many other ways Mr. Hepburn found an outlet for his charity. He founded, and acted as treasurer for no less than 37 years to, the Ogle Mews Ragged School, and of the Somers Town Blind Aid Society he was a vice-president. Mere statements of positions held, however, convey but an inadequate picture of the man. His deeds may not look different from those of many other men when reduced to mere historical records; but neither pen nor pencil can delineate the charm, the courteous bearing, and the warm-hearted geniality of Mr. Robert Hepburn.

#### CHARLES KING, M.R.C.S. ENG., L.S.A.

MR. KING, whose death was recorded lately at the age of 76 years, was born at Southampton. His medical education was pursued at Guy's Hospital and to the end of his life he reverted with constant pleasure and respect to the men of that school, particularly to Mr. Aston Key (for whom he acted as dresser), Dr. Addison, and others. After becoming qualified he was engaged for some time in the service of the Peninsular and Oriental Company and then he commenced practice in the City-road, where he remained for three or four years. Thence he removed to Highbury-park, where he succeeded Dr. Dobson who had recently died. Mr. King continued to practise there for 43 years, enjoying for the most part excellent health until a few months before his death, when he rapidly failed. He had a somewhat brusque and

Johnsonian manner but was a man of high character and was greatly esteemed by his patients and by his professional brethren.

#### HENRY DUNCALFE, M.R.C.S. ENG., L.S.A., J.P.

WIDESPREAD regret is felt at the death of Mr. Henry Duncalfe, which took place on Oct. 20th in his seventy-third year. Failing in health for some months past he left his home at Sutton Coldfield to undertake a course of treatment at the brine baths at Droitwich. On the evening preceding his death he was seized with an attack of heart failure, to which he succumbed a few hours later in the presence of his wife who had accompanied him. Mr. Duncalfe was born at Walsall, was educated at the Grammar School, and was afterwards apprenticed to Mr. Edwards, a surgeon of that town. Subsequently he entered as a medical student at Guy's Hospital, becoming a Member of the Royal College of Surgeons of England and a Licentiate of the Apothecaries' Society in 1851. He then joined Mr. Allerton of West Bromwich, and at the death of this gentleman some three years later he acquired the practice which he developed into a large and prosperous undertaking. His strength was hardly equal to the continued strain of the size to which his practice grew and in 1874 he ceded his work to his partner, Mr. A. P. Evans, and retired to Sutton Coldfield. Here he acquired a small practice and a sphere congenial to his tastes and habits, forming a circle of friends who held him in the highest regard and esteem.

Mr. Duncalfe became associated with the public work of the borough of Sutton Coldfield and was elected warden and chief magistrate under the old corporation. He took an active interest in educational matters also, being a governor and chairman of the Grammar School Board. Subsequently his name was placed upon the commission of the peace for the county of Warwick, where his judgment, his fairness, and his impartiality were always respected.

Mr. Duncalfe was an accurate observer of nature. As a student of natural history in his early days he formed a large and interesting collection of butterflies and moths. His tastes were largely of a scientific order and in this direction led him to precision and cleverness in his professional practice. In 1862 he was elected president of the Birmingham and Midland Counties Branch of the British Medical Association and he contributed several papers of practical interest to the branch. As a sagacious counsellor, a firm friend, and a public-spirited citizen his name will long be remembered. He leaves a widow and a daughter to mourn their loss.

## Medical News.

**SOCIETY OF APOTHECARIES OF LONDON.**—In October the following candidates passed in the subjects indicated:—

**Surgery.**—C. E. C. Child (Section II.) and G. B. Dixon (Sections I. and II.), Charing Cross Hospital; P. J. Fitzgerald, Dublin; I. Griffith (Section I.), London Hospital; W. B. Harris (Section I.), St. Mary's Hospital; D. Morrow (Sections I. and II.), Middlesex Hospital; and W. Parker (Section I.), Manchester.

**Medicine.**—D. E. Lockwood (Section II.), Royal Free Hospital; E. E. Naggjar (Sections I. and II.), St. Mary's Hospital; W. Parker (Sections I. and II.), Manchester; and F. M. Payne (Section II.), Royal Free Hospital.

**Forensic Medicine.**—E. C. Curtis, Charing-cross Hospital; R. Gillett, Royal Free Hospital; and E. E. Naggjar, St. Mary's Hospital.

**Midwifery.**—T. J. M. Clapperton, King's College Hospital; A. F. Heald, Cambridge; P. S. Hopkins, London Hospital; H. Johnson, Guy's Hospital; G. F. G. de Laubenque, Middlesex Hospital; T. G. Miles, Guy's Hospital; W. Parker, Manchester; H. Richardson, Leeds; C. W. Smith, Sheffield; and A. Turner, Charing-cross Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—C. E. C. Child, G. B. Dixon, P. J. Fitzgerald, D. Morrow, E. E. Naggjar, and H. Richardson.

**UNIVERSITY OF EDINBURGH.**—At the special graduation ceremonial held on Oct. 19th the following degrees were conferred:—

**Degrees of Bachelor of Medicine and Master in Surgery.**—Clarence Granville Hey, England; Arthur Hutton M'Shine, Trinidad; Albert Cormac Peterson, Australia; Percy Wilfred Shepherd, England.

**Degrees of Bachelor of Medicine and Bachelor of Surgery.**—Arthur John Brock, Scotland; Alfred Brown, Scotland; John Webster Duffus, M.A., Scotland; John Munro Dupont, England; William

Francis Lucius Austen Holcroft, England; John Jamieson, Scotland; Ernest Winbolt Lewis, India; Harriet M'Cloghry, Ireland; John Bryce M'Cutcheon, Ireland; Lionel Alexander MacMunn, England; Kenneth Duncan Cameron Macrae, Scotland; Antoine Felix Gaston Masson, England; Robert Murray, Scotland; Peterswald Pattison, Scotland; George Archibald Park Ross, Scotland; Richard Rutherford, Scotland; George William Smith, Scotland; Charles William Somerville, Scotland; William Casswell Spooner, England; George Henry Steven, Scotland; George Cecil Strathairn, Scotland; James Paget Thorne, England; Noel Nathaniel Wade, Wales; Ernest Alexander Walker, Scotland; Douglas Larmer Wall, England; Harold Edgar Wareham, England, and Philip Weatherbe, Canada.

*Special University Certificate in Diseases of Tropical Climates.*—Antoine Felix Gaston Masson, M.B., Ch.B.

*Degree of Bachelor of Science.*—Joseph Samuel Martyn, M.A.; and in the Department of Public Health, John Fleming Goodchild, M.D.

**OXFORD WOMEN'S AMBULANCE SOCIETY.**—The Mayor of Oxford (Mr. G. C. Druce), who is also president of the Pharmaceutical Conference of Great Britain and Ireland, distributed on Oct. 18th the certificates and medals awarded to the members of the society who had been successful in the examinations. There was a crowded attendance of ladies. Mr. E. C. Hale Jessop (honorary secretary) stated that since February, 1899, 396 had attended the classes, 265 had entered for the examinations, and 211 had received certificates. The ladies also had three nursing classes, 52 receiving certificates. The figures went to prove that the ladies took far greater interest in the work than the men. The mayor congratulated the members on the results and made some sound remarks emphasising the need for precaution against the transmission of disease by dust, dirt, polluted water, and clothing.

**ROYAL COLLEGE OF PHYSICIANS OF IRELAND.**—At the stated annual meeting of the President and Fellows held on St. Luke's Day, Oct. 18th, Dr. W. A. Winter was elected a Fellow of the College.

**MEDICAL ALDERMAN.**—At the meeting of the Plymouth Borough Council held on Oct. 14th, Mr. John Henry Square May, M.R.C.S. Eng., L.S.A., J.P., was unanimously elected an alderman for the borough.

**LUNACY IN SOMERSET.**—At the meeting of the Somerset County Council held on Oct. 15th, it was reported by the Joint Lunatic Asylums Committee that there were 1320 lunatics (760 females and 560 males) on the books, as compared with 1300 for the corresponding date of 1900. The weekly charge to be made to the unions during the ensuing quarter has been fixed at 9s. 4d. per head.

**CENTENARIANS.**—It is stated that Mrs. Elizabeth Wilmot of Kirkby Laythorpe, near Sleaford, Lincolnshire, who is now in her 102nd year, was last September awarded a prize for needlework at a local industrial exhibition.—Mrs. Southall of Wellington-road, Edgbaston, Birmingham, last September celebrated her hundredth birthday in the midst of a large circle of children, grandchildren, and great-grandchildren. Till about 80 years of age she led a life of great activity and visited for 40 years in the service of the Aged Women's Society, of which she was one of the principal founders. Mrs. Southall attributes her longevity chiefly to her abstinence from intoxicants. She signed the temperance pledge nearly 70 years ago, and ever since that time temperance work has had her warmest sympathy. She was born in 1801 in Great Charles-street, Birmingham, and married in 1824 the late Mr. Thomas Southall of Bull-street, whom she has survived for 40 years.

**NEGLECT AT BIRTH.**—An inquiry was held at Newton Abbot (Devon) on Oct. 12th relative to the death of the new-born child of the wife of a soldier who has been in South Africa for two years past. The woman was delivered of the child on Sept. 17th with only her sister, a girl, aged 16 years, in the house. The sister wanted to fetch assistance, but the mother declined, as "she wanted to keep it quiet." The infant died shortly after its birth. The next day a medical man was called in and asked to give a certificate of still-birth. He declined to do so, and at the inquest he stated that the lungs were only partly inflated and added that if the child had been properly attended at birth it would probably have lived. The jury eventually returned a verdict that the infant had died through the wilful neglect of the mother in not procuring the necessary assistance at birth. The deputy coroner said that was tantamount to manslaughter and the woman was committed to take her trial at the assizes.

**UNIVERSITY OF CAMBRIDGE.**—From returns kindly furnished by the college tutors, it appears that the number of freshmen intending to study medicine at Cambridge is 115.

**A NEW SANATORIUM FOR CONSUMPTIVES.**—On Oct. 18th the Countess of Derby opened, in Delamere Forest, Cheshire, a sanatorium, the gift of Lady Willox and Mr. W. P. Hartley of Liverpool. The new buildings will be used in connexion with the Liverpool Hospital for Consumption and Diseases of the Chest. The sanatorium has cost nearly £15,000.

**GENEROUS GIFT TO FROME HOSPITAL.**—At a meeting of the Victoria Hospital and Nurses' Home Committee, held at the public offices, Frome, on Oct. 18th, Major Sheppard, one of the joint honorary secretaries, announced that Mrs. Chandless of Brighton had expressed her intention of giving £2000 to the hospital for the purpose of endowing two beds. Mr. Alfred Parsons, A.R.A., has offered to furnish the committee with a plan for the laying out of the grounds, which has been accepted.

**REMUNERATION OF A MEDICAL OFFICER OF HEALTH.**—At the Guildford County Court on Oct. 17th Mr. H. Beale Collins, medical officer of health of the borough of Kingston, sued the Guildford Rural District Council for £32 11s. for work performed in connexion with the preparation of the annual health report for the period January to July, 1900. It appeared that in March, 1900, Mr. Wellington Lake, medical officer of health of the Guildford Rural District Council, went to South Africa and died there on July 16th of that year. Mr. Collins made an arrangement with Mr. Lake to take over the duties of the latter as medical officer of health as a friendly act without any remuneration whatever beyond out-of-pocket expenses. The council requested him to make up the report for the half-year but declined to pay for the work. In giving judgment his honour said that during the period in question Mr. Collins was not a servant of the council, but Mr. Lake was the responsible person. After Mr. Lake's death there was no legal machinery to compel Mr. Collins to make out that report. He therefore gave judgment for the plaintiff for the amount claimed with costs.

**AN INSANITARY AREA IN BIRMINGHAM.**—In June last the Rev. T. J. Bass, vicar of St. Laurence's, Birmingham, and 12 ratepayers connected with that church signed a requisition calling attention to the insanitary condition of a portion of the parish extending to 14½ acres. This requisition, which has been presented under the Housing of the Working Classes Act, 1890, stated that the annual death-rate in this area was about 40 per 1000. A report by Dr. Alfred Hill, the medical officer of health, was to the effect that the number of dwelling-houses in the area was 589, with a population of 2429. The district included many non-residential spaces, such as works, factories, and yards. If the area allotted to the dwellings only were taken into account the number of persons per acre was 272, as against 41 per acre for the whole city. The houses seemed to combine all possible sanitary defects. The Birmingham *Daily Argus* says that under the Housing of the Working Classes Act, 1890, responsibility now devolves upon the city council, which may prepare an improvement scheme and submit it to the Local Government Board, or in the event of the corporation not seeing their way to take action they must lay the facts before the Local Government Board, who may hold an independent inquiry.

**"RETURN" CASES OF INFECTIOUS DISEASE.**—At a meeting of the Metropolitan Asylums Board on Saturday, Oct. 19th, the Hospitals Committee reported that they had considered a communication from the Local Government Board, enclosing a copy of a letter from the grandfather of a patient in one of the board's hospitals. The writer stated that his grandson, a convalescent scarlet fever patient, was discharged from the Northern Hospital on August 3rd, and four days afterwards was admitted into the Eastern Hospital, suffering from diphtheria, his sister being received into the same hospital, also suffering from diphtheria, two days later. Reports on this case had been received from Dr. Hague, the acting medical superintendent of the Northern Hospital, and from Dr. Cameron, the board's medical investigator of returned cases. From these reports it appeared that the patient was thoroughly examined before he was discharged from the hospital, and that there was then

no evidence of diphtheria or of his being in any way ill. On the day following his discharge, as the child did not seem very well, the mother appears to have taken him to see two separate practitioners, neither of whom diagnosed the case as diphtheria. On August 7th the child was visited by another practitioner both in the morning and evening, and on the latter occasion was certified to be suffering from diphtheria. The committee were informed that it was a matter of common experience for symptoms of laryngeal diphtheria to show themselves with great suddenness, and this appears to have been the case with the boy in question. The report was adopted.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

**BENNETTS, A. J., M.R.C.S., L.R.C.P. Lond.**, has been appointed Assistant Medical Superintendent of the Infirmary and Assistant Medical Officer of the Gordon-road Workhouse of the Parish of St. Giles, Camberwell.

**BIRD, ARTHUR CYRIL, M.R.C.S. Eng., L.R.C.P. Lond.**, has been appointed Honorary Surgeon to the Victoria Cottage Hospital, Sidmouth, Devon, vice A. Macindoe, resigned.

**BROWNLEE, ALX., L.R.C.P. & S.E., L.D.S. Edin.**, has been appointed Senior House Surgeon to the Ingham Infirmary, South Shields, vice H. Crechlar, resigned.

**BYGOTT, ALBERT HENRY, M.B. Lond.**, has been appointed District Medical Officer and Public Vaccinator for the Deritend and Bordesley Districts of the Aston Union, vice Flamank Marshall (deceased) and B. S. Robins.

**COLLINS, E. TREACHER, F.R.C.S.**, has been appointed to the newly created post of Ophthalmic Surgeon to the Charing-cross Hospital and Lecturer on Ophthalmology at the Medical School.

**CUTFIELD, A., M.R.C.S., L.S.A.**, has been appointed Medical Officer for the Urban District of Ross.

**DEACON, MARY STEWART, M.B., B.S. Lond., L.R.C.P. & S. Edin.**, has been appointed Medical Officer of Health to the Accra Town Council, West Africa.

**EVANS, C. W., M.B. Lond., M.R.C.S.**, has been re-appointed Medical Officer of Health for Bakewell for a further period of five years.

**FORSYTH, A. F., M.B., C.M. Aberd.**, has been appointed District Medical Officer for Kea and West Kenwyn by the Truro Board of Guardians.

**HICHENS, FRANK, M.D., B.S. Lond., M.R.C.S., L.S.A., D.P.H. Lond.**, has been re-appointed Medical Officer of Health for Redruth (Cornwall).

**JACKSON, D., M.D., L.F.P.S. Glasg.**, has been appointed Medical Officer for the Urban District of Hexham.

**LAMB, J. M. A., L.S.A.**, has been appointed District Medical Officer of the Poole Union.

**SUTCLIFFE, W., M.R.C.S., L.R.C.P. Lond.**, has been appointed Medical Officer of the West Bromwich No. 3 District.

**SYKES, WALTER, L.R.C.P., L.R.C.S. Eng., L.F.P. & S. Glasg.**, has been appointed Junior House Surgeon to the Birmingham and Midland Eye Hospital.

**THOMAS, J. C., M.D. R.U.I., L.F.P.S. Glasg.**, has been appointed Public Vaccinator for Metropolitan District, Victoria.

**WACE, R. H., M.B. Aberd.**, has been appointed District Medical Officer, Quarantine Officer, and Public Vaccinator at Onslow, West Australia.

**WILLETT, GEORGE GILMORE DRAKE, M.R.C.S., L.S.A.**, has been appointed Medical Officer for the Marksbury District by the Keynsham Rural District Council.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

**BELGRAVE HOSPITAL FOR CHILDREN.**—Honorary Dental Surgeon.

**BETHNAL GREEN INFIRMARY.**—Assistant Medical Officer. Salary at rate of £100 per annum, with furnished apartments, board, and washing.

**BRACEBRIDGE ASYLUM, near Lincoln.**—Junior Assistant Medical Officer, unmarried. Salary £125 per annum, with apartments, board, attendance, &c.

**CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.**—House Surgeon. Salary at rate of £50 per annum, with board and residence.

**COUNTY ASYLUM, Lancaster.**—Assistant Medical Officer, unmarried. Salary £150, increasing to £200, and on promotion to £250, with apartments, board, washing, and attendance.

**DUMFRIES AND GALLOWAY ROYAL INFIRMARY.**—House Surgeon. £50 per annum, with board and washing.

**ESSEX COUNTY ASYLUM, Brentwood.**—Fourth Assistant Medical Officer. Salary £150 per annum.

**GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.**—Assistant House Surgeon for six months. Remuneration at rate of £30 per annum, with board, residence, and washing.

**GRIMSBY AND DISTRICT HOSPITAL.**—Resident House Surgeon. Salary £30 per annum, with board, lodging, and washing.

**GROVE HALL ASYLUM, Bow, London, E.**—Junior Assistant Medical Officer. Salary £120, with board, apartments, attendance, and laundry.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.**—Resident Medical Officer. Salary £200 per annum, with board and residence.

**HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W.**—Senior Clinical Assistants for six months, renewable.

**INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.**—Junior House Surgeon. Salary £75 per annum, with residence, board, and washing.

**LEICESTER INFIRMARY.**—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

**LINCOLN COUNTY HOSPITAL.**—Senior House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

**LONDON HOSPITAL, Whitechapel, E.**—Aural Surgeon.

**LONDON TEMPERANCE HOSPITAL, N.W.**—Medical Officer for six months. Honorarium at the rate of 50 guineas per annum, with board and residence.

**MACCLESFIELD GENERAL INFIRMARY.**—Junior House Surgeon. Salary £70 per annum, with board and residence.

**ROTHERHAM HOSPITAL.**—Assistant House Surgeon. Salary £80 per annum, with board, &c.

**ROYAL SEA BATHING HOSPITAL, Margate.**—Resident Surgeon, as Junior for six months and then as Senior for the like period. Salary at rate of £80 and £120 per annum respectively, with board and residence. Also Honorary Visiting Surgeon.

**ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.**—Surgeon and Assistant Surgeon.

**RURAL DISTRICTS IN THE COUNTIES OF LEICESTER, RUTLAND, AND WARWICK.**—Medical Officer of Health. Salary £550 per annum (inclusive of travelling and other expenses).

**SALFORD ROYAL HOSPITAL.**—Two Honorary Medical Officers.

**SALISBURY INFIRMARY.**—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing. Also a House Physician under 30 years of age and unmarried. Salary £75 per annum, with board, lodging, and washing.

**SCHOOL BOARD TAUNTON SCHOOL, Highbury-grove, N.**—Medical Officer. Salary £125 per annum.

**ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, London, E.C.**—Honorary Physician.

**UNIVERSITY OF GLASGOW.**—Examiner for Degrees in Medicine and Science, with special reference to Chemistry. Salary £30 per annum. Also Examiners for Degrees in Medicine, with special reference to (1) Materia Medica and Therapeutics, (2) Zoology, (3) Practice of Medicine (Systematic and Clinical), and (4) Surgery (Systematic and Clinical). Salary for (1) and (2) £30 each and for (3) and (4) £50 each.

**WEST RIDING ASYLUM, Wakefield.**—Locum Tenens for three months. Salary £3 3s. per week, with apartments and board.

**WESTERN DISPENSARY, Rochester-row, Westminster, S.W.**—Attending Medical Officer.

**WESTERN GENERAL DISPENSARY, Marylebone-road.**—Honorary Physician.

## Births, Marriages, and Deaths.

### BIRTHS.

**ALEXANDER.**—On Oct. 14th, the wife of W. G. Alexander, M.B., M.S. Edin., of a son.

**LEVICK.**—On Oct. 16th, at Havant, to the wife of George Levick, a son.

**SANDALL.**—On Oct. 13th the wife of Thomas Edward Sandall, M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., of a daughter.

### MARRIAGES.

**ARMOUR-MITCHEL.**—At Cobourg, Canada, on Oct. 2nd, 1901, Marie Louise, daughter of the late Captain O. M. Mitchel, U.S.A., and stepdaughter of James Hoban, Esq., of Washington, D.C., to Donald John Armour, M.B., F.R.C.S. Eng., son of the Hon. the Chief Justice of Ontario.

**COOMBE-JOHNSTONE.**—On Oct. 22nd, at St. Barnabas, Beckenham, by the Rev. A. H. Cooke, M.A., Fellow of King's College, Cambridge, head-master of Aldenham School, assisted by the Rev. N. M. Morgan-Brown, M.A., minor canon of St. Paul's, and the Rev. George Griffith, vicar, Russell Coombe, M.A., M.D. Camb., F.R.C.S. Eng., of Exeter, to Eve Harriet Cartledge, eldest daughter of John Cartledge Hirst Johnstone, J.P., of Beckenham, and formerly of Hardwick Hall, County Durham.

**FOOKS-BAINES.**—On Oct. 16th inst., at the parish church, Naburn, York, by the Bishop of Sodor and Man (uncle of the bride), the Rev. Randall Vickers (vicar), and the Rev. Richard Freeman, Edward Verdon Russell Fooks, M.R.C.S., L.R.C.P., younger son of Walter Pemberton Fooks of Auckland, N.Z., to Hilda Jane Maud, daughter of William Mortimer Baines of Belt Hall, York.

**GOING-EDGECOMBE.**—On Oct. 16th, at St. Nicholas's Church, Blundell-sands, Robert Marshal Going, F.R.C.S., to Fanny Augusta, daughter of the late George Edgecombe.

**YOUNGE-RAWCLIFFE.**—On Oct. 17th, at St. George's Church, Hanover-square, London, Thomas M. Young, M.B., M.S. Edin., to Florence Annie, third daughter of Henry Rawcliffe.

### DEATHS.

**APLIN.**—On Oct. 21st, at Hill House Notts County Asylum, Alfred Aplin, M.D., M.R.C.S., L.R.C.P., aged 47, Resident Medical Superintendent of Notts County Asylum.

**BENNETT.**—On Oct. 18th, at his residence, Sloane-street, Francis Graham Bennett, M.R.C.S., L.S.A., aged 59.

**BENTHAM.**—On Oct. 15th, at Ellerslie, Willesden, London, N.W., Robert Bentham, M.D. Aberd., aged 81.

**HOLDING.**—On Oct. 17th, at East Hendred Rectory, the residence of his son-in-law, Charles Holding, F.R.C.S., late of Victoria-street, Westminster, aged 93 years and 9 months.

**PEETE.**—On Oct. 20th, at Great College-street, Brighton, Thomas Peete, M.D. St. And., M.R.C.S., L.S.A., formerly of Margate and Tunbridge Wells, aged 76.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### "HOW DISEASE IS SPREAD."

AT an inquest held by the East London coroner at Stepney on Oct. 10th, it was mentioned that six persons of one family, varying from the age of two years to 17 years, had been suffering from small-pox without being medically attended. None of the sufferers had been vaccinated. Two of the children had been attending school and the elder lad had been out at work. That such a state of things should exist is remarkable and but for the prompt action of a medical man another nidus of infection might have been added to the seriousness of the prevailing epidemic. At the same inquest the coroner mentioned that a woman living in the house of the above-mentioned family had been found drunk in the street and suffering from small-pox. On Oct. 15th a female inmate of St. Giles Casual Ward was certified to be suffering from small-pox and while the ambulance was being requisitioned the woman escaped from the ward. After exchanging and re-exchanging her clothes with a blind woman to escape discovery she was found the following day in a state of intoxication on a doorstep in the parish from which she escaped. She was covered with eruption. Had the woman not been discovered she would have slept for the night in a house let in tenements and the consequences would perhaps have been serious. Great praise is due to Mr. Shirley Murphy and Mr. A. Wynter Blyth whose prompt action and zeal effected the woman's capture. Quite recently a man who had returned to Warminster from London was retained in the Warminster Workhouse suffering from small-pox. Another case of allowing children while suffering from an infectious disease to mingle with their fellows is also reported. In this case the child had been suffering from scarlet fever and was in the peeling stage. The bench, remarking that the public must be protected, fined the parent the ridiculously small sum of 2s. 6d. Dr. J. C. Thresh, the medical officer of health of Chelmsford, has reported the following case. On Oct. 5th a medical man called on him saying that there was a case of diphtheria at Springfield which he wished removed at once. As the ambulance had just gone out for a patient and would not be back till very late Dr. Thresh agreed that the patient should be admitted to the infectious hospital if some way of removal could be found. Later, a cab conveyed the patient to the hospital, and after leaving the patient with the nurse the driver took the cab away, although he (Dr. Thresh) had given instructions that the vehicle should be disinfected. It was subsequently discovered that the driver was not told that he was conveying an infectious case, and that on leaving the hospital he drove a lady and gentleman to a dinner-party. The Chelmsford Rural District Council have decided to take proceedings against the father of the patient in this case.

### "QUERIES ABOUT NEW ZEALAND."

To the Editors of THE LANCET.

SIRS.—Referring to the correspondence in THE LANCET of Oct. 19th, p. 1094, under the above heading, *Sharland's New Zealand Journal* and the *New Zealand Medical Journal* are the only medical journals of the colonies. Particulars may be had from us.

We are, Sirs, yours faithfully,

43, London Wall, Oct. 19th, 1901.

SHARLAND AND CO.

### "QUO VADIS" CIGARETTES.

THE Ardath Tobacco Co., of 44, Worship-street, London, E.C., have submitted to us some specimens of Turkish cigarettes, the tobacco of which they state is of a particularly pure kind and free from "faking" and from "seenting" matter. We could certainly trace no glycerine or added saccharine matter or any odour not due to tobacco. The tobacco itself is a satisfactory quality of Dubec. The smoke is agreeably aromatic and free from pungency. It would be better, we think, if the cigarettes could be made thicker so as to diminish the ratio of paper to tobacco.

### ELECTRICAL MANIFESTATIONS IN THE TREATMENT OF DISEASE.

THE particular form of etheric disturbance known as electricity has without doubt a powerful influence upon nutrition, and treatment by electricity is nowadays, as our columns bear witness, on its trial as a means of combating various morbid conditions. Electricity itself can be used in varied forms or can be easily converted into light or heat. But inasmuch as the apparatus for producing it in any quantity is not capable of being moved about easily it is more convenient as a rule to bring the patient to the electricity than to reverse the process. Electrical institutions have, up to the present, so far as we know, never confined themselves to working as an adjunct to medical practitioners. They have always treated patients on their own account. The latest institution of the kind, however, claims, and we think with justice, to work solely with the medical profession. That is to say, a patient applying for treatment must be provided with a recommendation from a medical man, and the management of

the institution prefer that this medical man should superintend the treatment himself. The institution is known as "The Electrical Ozone and Light Treatment," 14, Hanover-square, W. The installation consists of a series of comfortable rooms and cubicles for electric light-baths. The patient lies, undressed, on a plate-glass couch where he is exposed to the radiations of two sets of incandescent lamps which are arranged both above and beneath the couch. Free perspiration is quickly induced and the patient is subsequently massaged by a trained operator. A d'Arsonval high frequency apparatus is used to ozonise the air of the cubicle during the exposure in the light bath, and this apparatus is also arranged for the direct application of high frequency currents to the patients, if required. There are separate rooms and a massage for ladies. We think that probably the most valuable therapeutic agent will be found to be the electric light-baths. The ozone, beyond keeping the air of the cubicles fresh, has, we should say, but little effect.

### OPEN-AIR SANATORIA FOR THE TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—I would be glad if any of your readers could kindly inform me of an open-air sanatorium for a consumptive patient. Terms from 10s. to 30s. a week. Patient is a case that has greatly improved while residing at a farm for the last six months, but requires further treatment. Has the National Association for the Prevention of Consumption, and other Forms of Tuberculosis been instrumental in establishing such sanatoria in the South or Midlands? If so, where? I venture to ask this, as some time has elapsed since you published an article in THE LANCET dealing with open-air institutions in 1899.

I am, Sirs, yours faithfully,

Oct. 21st, 1901.

J. T. V.

\* \* A few sanatoria have been established by private or local generosity and more are contemplated.—ED. L.

### THE ANDERSON FUND.

THE committee formed to appeal for aid for the widow and two sons of the late Mr. R. B. Anderson, F.R.C.S. Eng., beg to announce the following additional list of subscriptions from July 26th to Oct. 22nd. The total amount now subscribed is 73 guineas.

	£	s.	d.		£	s.	d.
Mr. Edmund Owen	2	2	0	Mr. W. F. Brook	1	1	0
Mr. Reg. Gilbert	2	0	0	K. W. M.	1	1	0
Dr. G. Danford	2	0	0	Mr. G. B. Forge	1	0	0
Thomas	2	2	0	Mr. A. H. Dodd	1	1	0
Dr. F. de Havilland	2	2	0	Dr. Collier	2	2	0
Hall	2	2	0	Dr. W. J. Branch	1	0	0
Dr. Connel	1	0	0	Mr. G. Jackson	1	1	0
H. C. M.	0	5	0	Mr. R. J. Page Smith	1	1	0
Mr. W. R. Burchell	1	1	0	Captain W. R. Battye			
Dr. Edmund Frost	2	2	0	I.M.S.	1	1	0
Mr. B. Balding	1	1	0				

Donations for "The late R. B. Anderson Fund" should be sent and made payable to the Manager, Union Bank of London, Chancery-lane, London. As it is proposed to close the fund at an early date intending subscribers are requested to send in their donations without delay. The Earl of Stamford is the chairman; Mr. Timothy Holmes, F.R.C.S., is the honorary treasurer; and Mr. Walter Monnington, 7, Fig Tree-court, Temple, E.C., is the honorary secretary of the Fund.

### "HOMES FOR EPILEPSY."

To the Editors of THE LANCET.

SIRS.—Your correspondent "M.D." in THE LANCET of Oct. 19th, p. 1094, should try to get his patient into the Magull Home for Epileptics near Liverpool or the Epileptic Colony near Chalfont St. Peter, Bucks.

I am, Sirs, yours faithfully,

Didsbury, Oct. 20th, 1901.

JOHN MILSON RHODES, M.D. BRUX.

### MEDICINE AND POLITICS IN FRANCE.

A LADY writing over the signature "Grace Corneau" in the *Daily Mail* of Oct. 19th gives some interesting details regarding the medical profession in France and the association of its members with politics. At the last election "the large number of 51 doctors were elected to the Chamber of Deputies," while "among the members of the Senate a surprising proportion of medical men were also returned." According to the writer, such a selection of legislators is an amazing circumstance, quite incomprehensible to an Englishman, and yet immediately afterwards she adduces reasons, which she characterises as adequate, why the career of medicine should be looked upon by our neighbours as the "road to rulership." From sunrise to sunset, sometimes far into the night, the country practitioner drives about in his little "cariole," having with him, besides his medicine case, all kinds of books, newspapers, and "revues" (magazines or pamphlets), which he distributes among his patients. At every habitation he stops to chat with the occupants, thus discussing politics from one year's end to the other. "It is not strange," adds Madame Corneau, "that under these conditions ..... the doctor propagates his political opinions, makes himself popular, and becomes ..... the preferred candidate of his 'concitoyens' (fellow-citizens)." Many young men in France regard medicine as one of the surest roads to public life, but it is sad to learn that they are driven thereto because "nothing is more ungrateful than the medical profession in the provinces."

A provincial practitioner's fees are described as "pathetically modest." For what are called "office consultations" the peasant pays from 1s. 2d. to 1s. 8d., and the latter fee, with 5d. a mile for "déplacement" is also the usual charge for a visit. Very frequently, however, the miserly sick man will evade the depletion of his well-filled purse by presenting his attendant with "a lean goose, a tough chicken, or a sack of mediocre potatoes." Incidentally Madame Corneau relates an amusing story in which mention is made of rather a novel kind of remedy. In Paris "there are a large number of 'médecins-fonctionnaires' (official doctors)," one of them being attached to the Comédie Française. During a performance an actress was suddenly taken ill and fell fainting on the floor. The ticket-taker, who apparently was present, had noticed the medical man's pass among those that had been presented, so "an 'ouvreuse' (a woman usher)" was hastily sent in front to summon him behind the scenes. Arriving post haste, the first thing the ostensible physician did was to order everyone out of the "loge," where the unconscious patient had been carried. Then approaching her he shook her gently and said: "Madame, I much regret, but I am only a hardware merchant. Dr. X—is out of town, and kindly lent me his pass; what ought I to do for you?" Upon this, so great was her surprise, the lady forthwith regained her senses!

#### TREATISES BY GALEN.

In the British Museum there are several Syriac manuscripts containing translations of treatises by Galen, dating from the seventh, eighth, and eleventh centuries and recently Professor Gottheil of Columbia University, United States, under the title of "Contributions to Syriac Folk-Medicine" has published a manuscript in the *Bibliothèque Nationale* which consists of extracts from Syriac materia medica (see *Journal of the American Oriental Society*, vol. xx.). They relate only to diseases of the eyes, scalp, ears, and throat. The manuscript is quite a late one, but a copy of evidently an ancient text, and is really based upon Galen's *περὶ συνθέσεως φαρμάκων τῶν κατὰ τόπους βιβλία*, l. (see Kuhn's Galen, vol. xii.). The remedies recommended are of the most absurd folk-lore description and in most cases are quite useless, and we only allude to their publication for the benefit of any reader who may be making a selection of such, sometimes unsavoury, medical matters, or of scholars desirous of knowing any manuscript that may throw light upon the correct text of Galen's works. A curious coincidence with regard to Galen and the New Testament may be mentioned here. In his "De Sanitate Tuenda" he tells us that the finest eye-salve was made at Laodicea. Now, in Revelations iii., 18, the "Angel," or personification of Laodicea, is advised to anoint his eyes with eye-salve, which thus evidently was connected with the products of the city.

#### CREAM DRINKS.

Messrs. Kops of Eagle Mills, London, S.E., are introducing a method of preparing temperance beverages which claims some notice. The apparatus consists in reality of a small portable churn by which the beverage is sharply agitated upwards and downwards. This is done by placing the beverage in a glass on the platform of the apparatus which moves rapidly up and down by means of a crank attached to a wheel provided with a handle. The effect of rapidly shaking milk in this way is to give it a peculiarly creamy and attractive flavour. A series of flavourings are prepared, including coffee, vanilla, strawberry, and raspberry, for use with the milk. The coffee and vanilla flavourings are particularly good and are evidently prepared by adding the genuine respective essences to crystalline sugar. We could find no objectionable ingredients in them. The apparatus may be hired and it may be seen in operation at many refreshment bars. In summer ice-scrappings may be used, while in winter the preparation may be warmed. An ice-plane for obtaining ice-shavings is included in the equipment. The method provides a decidedly wholesome beverage and is entitled to commendation since it is calculated to reduce indulgence in alcoholic drinks.

#### "DICKENS'S DOCTORS."

We have received from Messrs. Carnrick and Co., Limited, a little circular in which written testimonials to the merits of their preparations are interleaved with illustrations of the medical men portrayed by Dickens. Some of the sketches are happy, Mr. Losberne, for example, and Mr. Jobling. Mr. Chillip and Dr. Slammer do not realise our ideals. But, where is Bob Sawyer and where is Sir Tumley Snuffin? It will be remembered that Bob Sawyer did not remain merely a medical student. He eventually became a medical practitioner at Bristol, where, although he was not very successful, we feel certain that he was a more reputable representative of the medical profession than the titled attendant of Mrs. Witterly. Sir Tumley Snuffin is one of Dickens's cruellest portraits, exaggerated in the twopenny-coloured way in which the characters in "Nicholas Nickleby" are exaggerated, but possessing certain features of probability.

*Science*.—There are only a few cases recorded in which it has been possible to isolate with certainty the bacillus typhosus from suspected water-supplies during epidemics of enteric fever. Further, unless the specific pollution is continuous it is extremely unlikely that typhoid bacilli will be detected in a water if more than a week has elapsed since the actual pollution occurred. Thus in the case of the typhoid fever outbreak at Maldstone, Dr. J. W. Washbourn

made a bacteriological examination of the infected water about 10 days after the specific infection had taken place but he failed to find the bacillus typhosus though the presence of bacillus coli indicated sewage contamination. It is doubtful, also, whether in the Worthing epidemic the bacillus typhosus was identified though there was no doubt again about the bacillus coli. It follows, therefore, that as time elapses since the pollution occurs it is more difficult to detect it by bacteriological processes, and this is particularly so when waters of original purity are under examination. Bacteriological examination, however, is certainly a much more delicate means than chemical analysis of diagnosing sewage contamination although it may fail to reveal the specific pathogenic organism. It is possible that if the typhoid bacillus existed in a sample of water which was declared to be chemically pure no evidence of its presence would be gained on making a bacteriological examination some days after the water had been drawn. Many experts hold the view that a water containing typhoid bacilli could not show chemical purity. In their report on the Maldstone water Mr. M. Adams and Dr. Washbourn agreed that proof of pollution of water may be obtained either from chemical or bacteriological examination. In all cases it is necessary to examine a considerable quantity of the water for the specific organism of typhoid fever. Diagnosis, it seems to us, both by bacteriological and chemical means, can only be trustworthy, strictly speaking, by systematic periodical examination, the variations in the composition and flora being the surest sign-posts of danger.

K. M. D.—The Lunacy Act mentions only "idiots, lunatics, and persons of unsound mind"—a feeble-minded person need not (and often does not) come under such designation. There is in such a case no need of a licence, but our correspondent had better get a medical opinion as to the degree of feeble-mindedness present. It may possibly amount to imbecility which would require certification, and due notice would then have to be sent to the Commissioners in Lunacy. Nothing further is required (and no licence) if only one single patient is taken. If more are taken a request for licence must be made to the Commissioners in Lunacy, 68, Victoria-street, S.W.

H. C.—Articles on Delorme's operation for empyema will be found in the following papers: Contribution de la Chirurgie de la Poitrine. Te. Congrès de Chirurgie, Paris, 1893, page 422; Traitement des Empyèmes Chroniques par la Décortication du Poumon, Congrès de Chirurgie, Paris, 1896, page 379; Traitement des Empyèmes Chroniques, Académie de Médecine, Paris, Jan. 23rd, 1894, *Semaine Médicale*, 1894, page 36; also in an article by Cestan, *Archives Générales de Médecine*, 1897; and in one by Ferrier and Raymond, *Chirurgie de la Plèvre et du Poumon*, Paris, 1899, published by Alcan.

W. A.—Our pamphlet "Difficulties under the Infectious Diseases Notification Act" explains the situation. As a general rule each informant is entitled to the fees.

X. Y. Z.—We regret to be unable to suggest an institution. There is, as yet, no accommodation of the kind for persons unable to pay, and to pay well, for it.

ERRATUM.—In our analytical notice last week of the baking powder made by the Fosco Manufacturing Co., the proprietary title of the preparation, and of the company also, should have been written Fosco and not "Phos. Co."

#### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Stewart's Instruments.)

THE LANCET Office, Oct. 24th, 1901.

During the week marked copies of the following newspapers have been received:—*Wiener Medicinische Blätter*, *Leeds and Yorkshire Mercury*, *Yorkshire Post*, *Liverpool Daily Post*, *Mining Journal*, *Surrey Advertiser*, *Thrapston and Randa Journal*, *Scranton Weekly Republican (U.S.A.)*, *Daily Argus (Birmingham)*, *La Belgique Médicale*, *Coventry Reporter*, *Scientific American*, *Bristol Mercury*, *Standard*, *Optician*, *Indian Engineering*, *Montreal Medical Journal*, *Boston Medical and Surgical Journal*, *Journal of Physical Therapeutics*, *Berliner Klinische Wochenschrift*, *Building News*, *Reading Mercury* and *Oxford Gazette*, *Glasgow Daily Record*, *Windsor and Eton Express*, *Globe*, *Yorkshire Herald*, *Pall Mall Gazette*, *Allgemeine Medicinische Central-Zeitung*, *Hertfordshire Mercury*, *Canadian Practitioner and Review*, *Fitzslove Visitors List*, *Journal of Commerce*, *Hong-Kong Weekly Press*, *Jewish World*, *The Torquay Directory* and *South Devon Journal*, &c.

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (28th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (29th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Bar (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY (30th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY (31st).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY (1st).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**SATURDAY (2nd).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## SOCIETIES.

**MONDAY (28th).**—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Paper: Dr. A. Elliott and Dr. J. W. Washbourn, C.M.G.: Typhoid Fever in South Africa. (Council Meeting Night.)

**ODONTOLOGICAL SOCIETY OF GREAT BRITAIN** (20, Hanover-square, W.).—7 P.M. Council. 8 P.M. President's Inaugural Address. Communications:—Mr. F. C. Wallis: Misplaced, Unerrupted Wisdom Tooth treated by External Operation.—Mr. J. G. Turner: The Teeth of Cetins and Microcephalics.—The President and Mr. L. Payne: Notes on the Dentition of Sphenodon.

**WEDNESDAY (30th).**—BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. General Meeting. Ordinary Meeting. Address by Dr. D. Kerr (in-coming President). Paper:—Dr. Houchin: Aix Treatment of Syphilis in London.

**THURSDAY (31st).**—NEUROLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Cases:—Dr. Ferrier: A Case of Successful Removal of Cerebellar Tumour.—Dr. Ferrier and Dr. A. Turner: A Case of Successful Removal of a Cerebral Tumour. Dr. Hutchison: A Case of Hemiplegia with Mental Deficiency in a Child.—Dr. Head: (1) A Case of Muscular Atrophy, probably of Neuritic Origin; (2) A Case for Diagnosis; (3) A Case of Wrist-drop. Dr. Muskens will demonstrate Lantern Slides illustrating the Segmental Distribution of Sensory Changes in Tabes and Epilepsy.

**FRIDAY (1st).**—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith-road, W.).—8.30 P.M. Ordinary Meeting.

**LARYNGOLOGICAL SOCIETY OF LONDON** (20, Hanover-square, W.).—5 P.M. Cases will be shown by Mr. Spencer, Dr. Donelan, Dr. St. Clair Thomson, Mr. Westmacott, Dr. Tilley, Dr. St. George Reid, Mr. Lake, and Mr. Waggett.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY** (Royal Kent Dispensary, Greenwich-road, S.E.).—8.45 P.M. Paper:—Mr. G. C. Williams: High Frequency Electrical Currents in the Treatment of Certain Diseases.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (28th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. M. Morris: Clinique. (Skin.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Ball: The Examination of the Throat and Nose.

**TUESDAY (29th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. H. Campbell: Clinique. (Medical.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Minor Surgery.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC** (Queen-square, Bloomsbury).—3.30 P.M. Dr. Ferrier: Amyotrophic Lateral Sclerosis.

**WEDNESDAY (30th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. A. H. Tubby: Clinique. (Surgical.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Eccles: Surgical Anatomy.

**LONDON THROAT HOSPITAL** (204, Great Portland-street, W.).—5 P.M. Dr. Stoker: Impaired Movements of Vocal Cords. (Post-Graduate Course.)

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (Brompton).—4 P.M. Dr. Perkins: Pneumothorax.

**CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL** (Gray's Inn-road, W.C.).—8 P.M. Dr. D. Grant: The Examination of the Throat and Nose.

**THURSDAY (31st).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Keetley: The Operative Treatment of Fractures.

**THE HOSPITAL FOR SICK CHILDREN** (Gt. Ormond-street, W.C.).—4 P.M. Mr. Collier: Clinical Demonstration.

**CHARING-CROSS HOSPITAL.**—4 P.M. Mr. Boyd: Surgical Cases. (Post-Graduate Course.)

**LONDON TEMPERANCE HOSPITAL** (Hampstead-road, N.W.).—2 P.M. Dr. S. Fenwick: Clinical Demonstration.

**FRIDAY (1st).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. R. Lake: Clinique. (Ear.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Therapeutics.

**LONDON TEMPERANCE HOSPITAL** (Hampstead-road, N.W.).—2 P.M. Dr. P. Parkinson: Clinical Demonstration.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Office, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.

Subscriptions (which may commence at any time) are payable in advance.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

# A GENTLE HINT.

## Pirates.

In a spasmodic way they appear now and then on the scene. They make bungling work of it. They copy what they think will do them most good, and not one of them has had the manliness to as much as say—"By your leave, sir." They

A Pirate of ye  
Olden Time—called  
a Knave  
in those days.

copy our advertisements, or the "Titles" we originate, to make people believe that theirs are ours; they have used our trade names which we have made popular and valuable by expenditure and work; they denounce the improvements we introduce, until, in spite of their underhanded manoeuvres, we secure the just appreciation of the profession, and then they make imitations of our products in appearance, though not in quality; and in divers ways

seek to deceive the profession and steal our thunder.

To us it appears truly humorous that amongst them firms whose antiquity is their prime boast, and whose traditions harp upon the integrity of ancestral founders, should play such catch-penny antics. Having won by genuine merit and originality the confidence of the profession and trade, we can, so far as we ourselves are concerned, regard these puny pirates with contempt, but it is our duty to protect our friends.

When the lame man made a bargain with the blind man for the latter to carry him, they were neither of them in business worth mentioning, and the bargain was mutually advantageous; but for one who might both walk and see to saddle himself on to another is not delicate, to say the least. We feel that we can see and walk, and when those who might do the same try to ride on our industry it seems our bounden duty to point out to them how unbecoming their conduct really is.

We have become more or less used to imitators, and when the thing is done right handsomely it almost seems like a compliment; but to be a compliment it should certainly be free from the semblance of fraud. "Me too" has ever been the motto of trade pirates, and of those who have lost their grip, and of those who never deserved.

For the edification and comfort of our imitating neighbours we offer an allegory—it is a very ripe "chestnut," but a sound one, and here it is. Once upon a time—not so very long ago—as the story goes, a company of soldiers was garrisoned in mountain wilds where there were Indians on the war-path. One day a tribe of the Red Men were spied in a valley, and the troops were forthwith ordered out in great haste. They strapped a cannon on the back of a mule, and hastened away to give battle. When they reached the crest of a cliff they saw the war-dancers in the valley below.

They had no time to dismount the cannon, so turned the

mule about as a gun-carriage, and fired. The howitzer "kicked" so tremendously that it knocked the animal off his legs, and cannon and mule rolled precipitately down the mountain into the midst of the Indians, frightening them nearly out of their wits, and they beat a hasty retreat—all but one, who was so paralysed with fear that he allowed himself to be captured and taken to the camp. When interrogated as to why he allowed himself to be taken, he exclaimed—"Me no 'fraid soldier man, me no 'fraid cavalry man, but when live jackasses fired me, me think the devil must be near."

Though we do not confess that we are timid, the Indian's case is in some respects like our own. Legitimate business warfare may be engaged in with satisfaction, and we heartily applaud all new improvements and legitimate enterprises from whatever source they come; but who could desire to have trade "jackasses" precipitated upon them as competitors?

Now, Imitators, we enjoin upon you to discard your schoolboy mimicries. We don't expect much of you.

Still, "Be not too bold!" "Assume a virtue if you have it not." When you want a new name for one of your products (or imitations) give it a name that does not deceive. Give it a name that has not been made valuable by others' expenditure and industry.

Give it a name that, when you make your sales, you can say to yourselves—"These do not rightfully belong to another." What is it to appropriate a trade name but to take what another has laboured for and that may become in all equity his means of subsistence.

He Would Gather Other Men's Fruit.

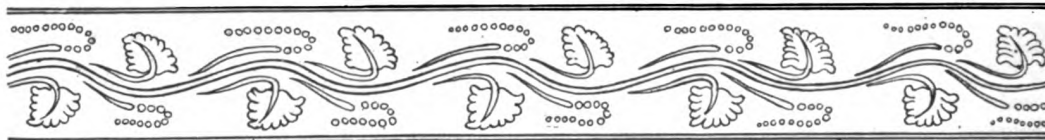

Sales thus made are dearly bought. We would suggest that those whose enfeebled intellects prevent them from creating anything original, and who find it necessary to copy the titles of our articles or advertisements, might consult a dictionary—there are upwards of 60,000 English words to choose from.

The substitution of a stone when asked for bread, was one of the earliest arts of knavery; but this never won faith or honour. The modern substituter of crude medicines to increase his profits shrinks not from injuring both physician and patient.

Those who have, through inadvertence, trespassed upon our rights, and who have made the *amende honorable* when we have called their attention to the trespass, we acquit of all wrong intent, and can but respect their frankness and honesty of purpose. Everyone is liable to tread unwittingly upon the rights of his fellow-men, but an honest man is ready to admit his fault and relieve his conscience. Wilful trespassers, who persist in wronging us, and thereby render themselves liable under the law, we have punished and shall punish with the utmost severity. Those who wilfully trespass upon our rights, but cunningly evade the liabilities of the law, we shall expose to the ignominy they so justly deserve.

BURROUGHS WELLCOME & Co.

LONDON and SYDNEY.

## 'KEPLER' SOLUTION

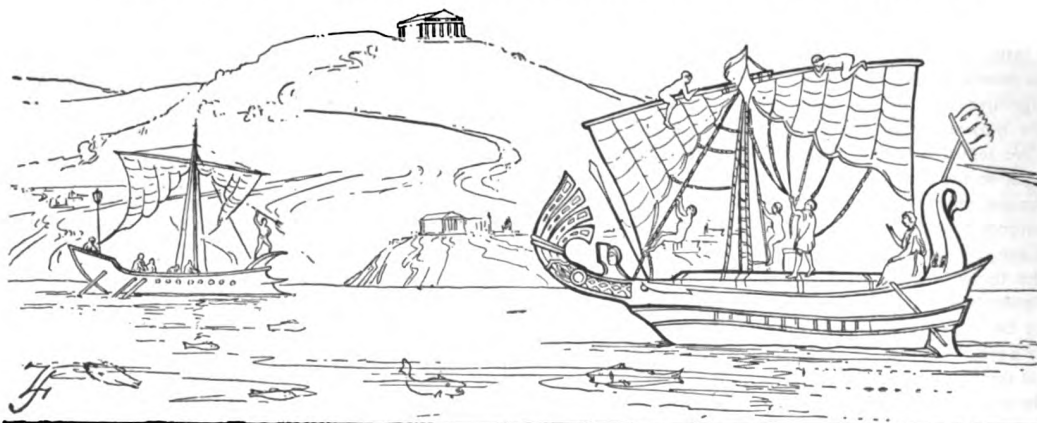

Of the finest Norwegian Cod Liver Oil in 'Kepler' Malt Extract, contains the richest force-producing and tissue-forming elements known. Extremely palatable, easily digested, and readily assimilated, 'Kepler' Solution has long been recognised by the medical profession as a standard product.

"Its superiority as a therapeutic agent is obvious."—*The Lancet*.

*AVOID CHEAP AND WORTHLESS IMITATIONS. They disappoint the physician and harm the patient. Always insist on obtaining the genuine 'KEPLER' PRODUCT.*

*'Kepler' Solution is supplied to the medical profession in small and large bottles at 1s. 8d. and 3s. per bottle.*

Burroughs Wellcome and Co., LONDON and SYDNEY.

*On their return from a successful expedition it was customary with the fishermen of ancient Greece to offer sacrifices to Poseidon:—*

"Then did a whistling wind begin to rise,  
And swiftly flew we through the fishy skies,  
Till to Geræstus we in night were brought,

Where, through the broad sea since we safe had wrought,  
At Poseidon's altars many solid thighs  
Of slaughtered bulls we burn'd for sacrifice."

A Lecture  
OR

METALLIC POISONING.

*Delivered at the National Hospital for the Paralysed and Epileptic, Queen-square, W.C., on Oct. 22nd, 1901,*

BY SIR W. R. GOWERS, M.D. LOND., F.R.S.,  
PHYSICIAN TO THE HOSPITAL; CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—Metallic poisoning has occupied a considerable amount of public attention during the last year. The epidemic of arsenical poisoning caused by the contamination of beer and the consternation it produced will be fresh in your minds. Many of you may also have noted the efforts which have been made to lessen the amount of lead-poisoning incidental to the process of glazing pottery and the difficulty there is in practical prevention. Such cases of lead-poisoning as occur in trades appeal to the public by their concentration and by the apparent possibility of their prevention. But that which occurs in such industries is but a trifling proportion of the whole amount in the kingdom, most of which occurs among those who are engaged in the work of renewing for us the freshness and fairness of our habitations—the house-painters.

Here, for your observation, are two patients suffering from the effects of lead on the nervous system and I wish to avail myself of their presence to impress upon you some facts regarding metallic poisoning. Some of them they illustrate, others they do not. Both patients exemplify the fact I have just mentioned—both are house-painters. One presents the characteristic effect of the disease—wrist-drop and paralysis of the extensors in the fore-arms—and the other does not. I think I may assume that you are familiar with the features of this paralysis and I need not describe them in detail. Some points will come before us presently. But the case to which I would first and specially direct your attention is that of the patient who has no paralysis. He can move his hands freely and well. He is suffering from various symptoms of feebleness of the nervous system. He is weak generally, although, as you see, he is fairly nourished. He can only walk with difficulty, but there is some cause for this, as we shall see. He complains of numbness at times in the right foot and left thigh. He has had much headache, and when he holds his hands out they present fine tremor, to which we must return. His difficulty in walking is partly due to an injury long ago. In 1888 he sprained his right ankle so severely as to be in the Bristol Royal Infirmary for four months. Some weeks after his discharge he injured the instep on the same side. The injury seems to have led to disease, because he returned to the infirmary and some bone was removed. Contraction in the calf must have followed, for the Achilles tendon had afterwards to be divided. Subsequently a toe was removed—why we do not know. He slowly recovered and was able after a time to resume work, but after working for some time he again lost strength and his left leg became thin. His weakness culminated in an attack of colic. This was six years ago; only after long abstinence from work did he gain enough strength to resume it, with, after a time, a similar result. After another attack of colic a year ago he was so much more feeble that he had to give up and has not worked since. During the last year he has suffered also from much headache and from the trembling of the hands. The weakness of the legs has also become so much worse that he was only able to walk with crutches until he came into the hospital seven weeks ago. Yet apart from the tremor there is little that is objective to correspond to his disability. His knee-jerks are rather active, but he presents no foot-clonus. His left leg is thin and his foot shows traces of the operations he has undergone. His muscular strength is small and movements are rather jerky and not sustained. When I first saw him he had been carefully examined and notes had been taken. I was told that it seemed to be a case of "simple neurasthenia." I looked casually at the bed-card and at once my eye was caught by the record of his occupation, "Painter." I looked from the bed-card to his gums and there I saw written in equally distinct characters

No. 4079.

the record of the effect of his occupation in a conspicuous lead-line. Further inquiry elicited the fact of the two attacks of lead-colic which I have mentioned, one six years ago and one a year since, but also that he had never suffered from any degree of wrist-drop.

Let me interrupt my special subject for a moment. The history of the word "neurasthenia" is noteworthy. It is a contribution to medical nomenclature which we owe to our Transatlantic brethren, and it attained universal use with the utmost celerity. The concise and concrete character of the word gives it a satisfying definiteness. This depends to a large extent on its classical and somewhat graceful sound. Not only is it graceful to the ear, but it is grateful to the mind of the patient who suffers and longs to know from what, who longs to have a name for that which he, or more often she, feels must be a more definite malady than is suggested by the common-place designation of "nervous weakness." How far the practical utility, which, if low, is definite, has influenced its use I cannot say. But its use has extended far beyond the needs of the patient, and indeed did so from the first. It has firmly established itself in current clinical terminology. But it often tends to be too satisfying. Men are apt to rest on it as they would not on its English equivalent. If they do not actually think that they have found the malady from which the patient is suffering, an influence is exerted on them in that direction of which they are unconscious, which lessens the tendency to go further in the search for the whole morbid state. Words are our servants, but they often exert a very masterly influence upon us, none the less effective because we are not conscious of it. They have also their own vitality, feeble or vigorous, and we have little power to influence their career. This fact has come distinctly within my own experience. I have to confess to the authorship of two words. One, "myotatic," was always a puny infant, and I doubt whether it still maintains an independent existence. The other, "knee-jerk," instantly attained universal use, and, indeed, I think has seemed to most persons to have sprung spontaneously from the thing itself, without suggestion—perhaps the greatest compliment a word can pay. But the general use at once achieved by "neurasthenia" was in spite of a strong objection to it which was felt by many. The Royal College of Physicians of London could not include it in their "Nomenclature of Disease," and yet it is now one of the most common of medical words in every language. It would be instructive in more than one way to have a careful study of the forces which have influenced its career, but that I cannot attempt. We must, I think, admit that not only is it a satisfying word to those who suffer, but it has a certain convenience which has almost compelled many to employ it who at first objected. If I may be pardoned for a partial paradox, its convenience is not the less real because this rests on features that are illusory. Remember that the word is a name which should have little meaning, even to those who use it. You may employ it to collect the symptoms of the case under a general designation, but do not let it cover them as a cloak.

When we had ascertained the facts I have mentioned it was impossible to doubt that the patient was the subject of lead-poisoning or that his symptoms of nervous weakness had the same origin. They had developed after he had passed from the hands of the surgeons and had gained strength enough to resume work. On each occasion it was after he had been at work for some time that he began to fail, lost strength, and suffered from the symptoms you have heard, and each relapse was attended by the colic which demonstrated the action of the toxic influence to which his work exposed him, and emphasised the relation of the renewed weakness to this influence. That this influence is the effective cause of his symptoms, little as they would themselves suggest it, is shown by his history, and it is confirmed in an instructive way by careful observation of his state, especially of two features. The tremor he presents, which I will ask you to note carefully when I have done, is a fine tremor which occurs only on movement, but it differs from the tremor so often seen in hysterical and nervous persons. That is a general irregular movement of the hand and fingers. Here you will observe that there is a quick lateral movement of the fingers, the result of contractions in the interossei. This is a peculiar and unusual feature, suggesting a special cause. Tremor is well known to be a result of lead-poisoning, and you know that it is a characteristic effect of the toxic influence of another metal—mercury. The second indication that he is still suffering

from the influence of lead on the nervous system is very curious. It has been before observed, at least in Germany, but opportunities for detecting it are rare and are still more rarely utilised. You are familiar with the wrist-drop, which is a common effect of lead, the atrophic paralysis of the extensor muscles in the forearm. A good example of it is presented by the second patient before you. Such wrist-drop is due to neuritis and is accompanied by the characteristic "reaction of degeneration" to electricity—loss of faradaic and increase of voltaic irritability, and to the latter a change in polar response. In health, contraction occurs to a weaker current with the kathode, the negative pole, than with the anode, the positive pole. In the reaction of degeneration this order is reversed, the contraction occurs more readily with the anode. In this patient we found this polar change in all the muscles that would be affected in wrist-drop and in no others, although it was the only change in reaction that could be detected. All the other muscles of his limbs, including those of the legs, presented the normal order of response. I am sorry—I was going to say—that you cannot see this. He has improved so much during the last few weeks that on one side the order of polar response has become normal, and on the other side is on the way to be so, for the response is now equal to each pole. When he came in the lead in his system must have exerted a definite influence on the nerve-endings in these muscles: he must have been on the verge of wrist-drop. This condition thus affords us additional evidence of the present action of lead on his nervous system.

My object in showing you this case is that it may impress on you the great variety of symptoms to which lead may give rise and the importance of not overlooking the cause in consequence of the equivocal character of the effects. The variety of disturbance of the nervous system which lead may produce is very great. Indeed, you might be prepared for this when you remember how wide and severe are the effects of acute lead-poisoning, how gravely the brain itself suffers in some cases, manifested by what is called "saturnine encephalopathy," often attended by optic neuritis. In more chronic cases the symptoms seem to depend on the momentum with which the poison acts and on the predisposition which the individual possesses. Let me enumerate those derangements which I remember to have met with. Lead may cause not only the common peripheral neuritis but a slower chronic atrophy of the muscles, seen first in the interossei; it is precisely like spinal atrophy, and probably such, but differing in that it does not progress if its cause ceases to act, although it is far more enduring than the wrist-drop; it may be permanent, though it does not increase. Lead may cause some forms of sclerosis of the cord, usually slight in degree; it may cause optic nerve-atrophy; and many forms of functional disorder may result from it. It may cause tremor, as you see in this patient; chronic convulsions, like those of epilepsy; and hysteria, with its varied manifestations, in predisposed subjects. Neuralgia, sometimes of great severity, may be due to it, and headache is a frequent effect, as well as the symptoms of general nervous weakness. In all such cases, in which there is nothing in the symptoms to suggest the cause, this may escape you, unless you are put upon its track either by the occurrence of other associated cases of lead-poisoning, by the occupation of the patient, or by the presence of its great sign, the lead-line on the gums. Let me dwell briefly on the line, because thereon hangs one of my lessons. It is typical in proportion as it approaches Euclid's definition of length without breadth, always provided it is black. It is said to be blue, but I have never myself been able to see any colour in it. It is not always to be seen and often it is not to be seen readily. You know, or should know, the reason why it may be absent even in the most pronounced cases. It is the edge of the deposit of sulphide of lead beneath the inner surface of the gum, where this is separated from the teeth even in a very slight degree. The sulphur comes from albuminous substances which decompose there. Sometimes you see a similar deposit in the mucous membrane of the lower lip, when there is tartar on the teeth with which it comes in contact. Tartar contains organic substance mixed with earthy salts from the saliva and it yields enough sulphur to act on the lead. We have not this deposit in the patients here to-day. But I should like you afterwards carefully to compare the line which is present in each. In the first it is conspicuous, but it is not continuous; it is in separate pieces, where the gums are more detached. The second patient has always been particular

about his teeth and careful about cleanliness—hence the detachment of the gums is slight; and although the line is present everywhere it is extremely narrow and only seen on looking closely. Indeed, it was altogether missed at first. When looking for a lead-line use your ophthalmoscope lens, which I presume you are never without. Careful as this patient has always been, he must have gradually accumulated lead in his system, but his final breakdown, with the wrist-drop which you see, he attributes to a cause which it is well to note. He ascribes it, apparently with reason, to the work of painting some ceilings. In this work the man who paints has to stand below that which he is painting, and it is impossible for him to avoid inhaling some of the spray which his brush necessarily throws off—spray which may be loaded with lead. It must be the most perilous form of painting. I wish that the rich who indulge in the luxury of painted ceilings knew at what price it has to be paid for, not by them, but by those who produce the special beauty they desire. I think that house decorators ought to make the fact known to those who ask for this superfluity, for such it certainly is.

But I have not quite done with the lead-line. Far more common than the rare cases in which it is quite absent are those in which it exists only in fragments, often much smaller and fewer than in this patient. It may be at only two or three isolated spots or on the tips of the projections of gum between the teeth. It can then only be found by a most careful and thorough search on the upper jaw as well as the lower. But remember that the smallest fragment, if distinct, is as significant as the most extensive deposit. A year or two ago a patient came to me from the other side of the world and said that he was suffering from muscular wasting. I found considerable atrophy of the muscles of the forearms, but it was of the muscles that suffer in lead-poisoning, with characteristic wrist-drop as its result. No others were affected. They had lost faradaic irritability and presented very little voltaic irritability, but this is common after a time in such cases if voltaic electricity has not been applied. The excitability to voltaism quickly improves in this state after a short course of treatment with it. The onset had been subacute, just as it commonly is from lead. Of course, I at once examined his gums. At first sight they seemed normal, but on more thorough inspection, and especially on examining the gums of the upper jaw, several spots were found at which there was a slight separation from the teeth, and there I found two or three indubitable fragments of lead-line. I afterwards also found some black points at the ends of the projections between the teeth of the lower jaw. I could ascertain no source for the poisoning. The patient was a grocer, but had not for years been accustomed to handle the lead-paper by which tea is protected. Still, I could not doubt that he was suffering from simple lead-palsy, and I therefore felt justified in giving him a very hopeful opinion, a prospect of steady although slow improvement under treatment. The forecast was entirely justified. He went home in a year's time almost well. But I should not have spoken so strongly had I known what he afterwards told me. After I had expressed my opinion he said that he had been sent to England as a sort of forlorn hope. He had been told that he was suffering from progressive muscular atrophy which nothing was likely to arrest. His own words were that he started under what he "felt to be a sentence of death." Perhaps he exaggerated. It is always well to remember the advice once given by a wise physician: "Never believe anything a patient says that another doctor said." But if he had told me this before, I should have been less emphatic. I should have given him some hope and should have allowed this to be gradually augmented by his experience. It is always desirable to avoid expressing a difference of opinion more strongly than is absolutely necessary. And I heard of it again. But I cannot doubt that the cause of the palsy might have been discovered by a sufficiently minute search, and it is to impress the importance of this upon you that I tell you of the case. It is an illustration of one of the wise sayings which the late Sir William Jenner was wont, I might almost say, to stick into the minds of his pupils, "More mistakes are made, many more, by not looking than by not knowing."

But there is one last resort for the detection of this cause of palsy. If the symptoms are such as to suggest lead, and you are sure that there is no trace of lead-line in any part of the gums, you may feel confident that it is not at work, provided the state of the gums certainly is such as to give rise to it. If the gums are everywhere perfect you cannot feel thus

sure. I have seen saturnine wrist-drop without a trace of line, but there was no room for doubt; the case was one of the many which occurred in Sheffield in consequence of the solvent power of the peaty water upon leaden pipes. Yet we have a source of information. If the case is seen early its nature may be decided by an analysis of the urine, especially after iodide of potassium has been given for a few days. It is a rather troublesome process, needing a large quantity of urine, but it may be decisive. I remember employing it in one case of wrist-drop perfectly like that of lead in distribution, course, and character. The result was negative, and its negation proved only too trustworthy; the extensor palsy was followed by a wasting elsewhere and general rapid progressive muscular atrophy.

I mentioned arsenic as another metallic poisoning which has loomed large in the public and professional eye. The extensive epidemic of arsenic-poisoning in the north has had at least one good result—a vast increase in the general professional knowledge of the subject, so that the facts which were previously familiar to a few are now known to all. But it may still not be quite useless for me to impress on you the need for fixing its signs on your mind, ready for revival, because the need for the knowledge may come when you least expect it. Like lead, it causes neuritis, but arsenical neuritis usually affects the legs before the arms. Moreover, its effects on the nerves vary much; the common palsy may be absent, and the sensory nerves may suffer much or most, and hence the symptoms may be equivocal and even misleading—sometimes, indeed, they may be identical with those of tabes.

Just as the line on the gums is the indication of lead, changes in the skin, especially certain forms of pigmentation, constitute the outward and visible sign of the influence of arsenic, visible at least if you look for them, and a sign if you know what they are like. They have been abundantly described, not only by Dr. E. S. Reynolds of Manchester, to whose perception of their significance we owe the discovery of the cause of the epidemic, but especially by Dr. H. G. Brooke and Dr. Leslie Roberts who have published a very full account of them and their pathology in the *British Journal of Dermatology* for April last. I only propose to mention some salient points regarding the pigmentation. Other changes are also common, especially the thickening of the skin of the palms and soles, but the pigmentation is that which is likely, as a rule, to attract attention, and is of most practical importance. Moreover, this Hospital is the only place at which you are at all likely to become practically acquainted with it. Arsenic alone enables us to prevent or lessen the troublesome eruption which bromide causes, and few patients who take the combination for more than two years escape pigmentation. In one case I was able to discern the precise amount which had been effective. The darkening of the skin was first distinct when the patient had taken liquor arsenicalis for two years in uniform quantities, and the total was 104 grains of arsenious acid, or two grains weekly. Doubtless slight signs of it would have been discerned sooner. But I think that if you look at the neck of many old cases of epilepsy attending here, you will meet with an example before long. The change is most marked on the skin of the trunk, front and back, but it extends to the limbs and also to the neck, where indications of it may be detected with least inconvenience. Given with bromide, arsenic has very little tendency to act upon the nerves, even when a sufficient amount has been taken to cause extreme pigmentation. I have a strong impression that it is most readily produced in those who are most prone to the bromide acne, but the impression must of necessity remain such, because the disposition to the acne leads to the administration of larger doses of arsenic.

Whether or not you are able to become acquainted with the aspect of the skin that is due to arsenic, it may serve you in good stead if you remember its occurrence and certain leading features. The brown pigmentation begins as small spots, which may commence, as I have seen, in spots of congestive redness, and the brown tint succeeds the red. These dark spots sometimes exist alone, more often they are seen chiefly on the outer portions of the most pigmented regions, where the tint is more uniform. The uniformity may be due to coalescence of the spots, but sometimes this diffuse colouration seems the first thing. The tint is that which is called sepia, a warm sepia or cold sepia, according to its duration, to use the terms employed by artists. It is not so dark as the pigmentation of Addison's disease and has not the same distribution. Although it is more marked

at places at which there has been pressure, it occurs irrespectively of this and is greatest on the parts of the trunk least affected in Addison's disease. When the small discrete spots coalesce they often leave small areas which are unpigmented and which have a pearly whiteness. Three weeks ago I saw a patient whose skin over the whole trunk was of a deep mahogany colour from this cause, with such white spots scattered over it. He was so prone to the bromide rash that even the dose of arsenic he was taking (seven minims with 25 grains of bromide twice a day) did not suffice to keep him entirely free. But he had been free from fits for 16 months and his parents would not hear of a reduction in either the bromide or the arsenic. The darkening of the skin, they said, was quite unimportant, and that is the common opinion of those who present it when they know its cause. I have constantly to explain to patients its origin and to give them the choice between the bromide spots and the darkening of the skin; there is never hesitation in choosing the latter. The white spots I have mentioned are common and somewhat characteristic, although they are met with in other forms of pigmentation. They have been called "rain-washed" spots from their scattered distribution, but their whiteness suggests a more potent agency than simple washing. I believe that their pearly whiteness is not the effect of contrast alone but that they are actually paler than the normal skin. Why such areas should not only resist the pigmentation but should apparently lose what they possessed, is a mystery which the pathologists have not, I think, explained. But we may note that there seems to be a curious solidarity in these pigmentary processes, in consequence of which excess may entail adjacent deficiency and, I may add, a deficiency may be attended by adjacent excess.

Perhaps you will allow me to digress for a moment to mention to you a very remarkable illustration of the latter fact—increased pigmentation in the vicinity of its diminution. I have described the case elsewhere, but it will probably be new to you. It is that of a man who had traumatic meningeal hæmorrhage over the left hemisphere. As a result of this, during the three days he lived after the injury, the right, opposite half of his brown moustache and beard became blanched so as to be almost white. The hair of the scalp was not affected. The change was watched during life and carefully noted after death. It was like that which has been described as the result of profound emotion, but it was due here to a physical agency. It can only be explained by assuming that the disordered innervation so changed the secretion at the roots of the hair as to produce a material capable of ascending the hairs and discharging their pigment. But after death we noticed another thing, which leads me to mention the case. The very grey, almost white, right half was separated from the natural brown left half by a narrow vertical line, or narrow zone, in the middle line, in which the hair had become almost black. Apparently where the disordered influence ceased in its extreme degree, at the blending of the innervation of the two sides, a change in the pigmentary process had occurred of the opposite character. Mysterious as the fact is, and perhaps impossible to explain, it illustrates the close relation between the *plus* and the *minus* in pigmentary processes. I am not sure that we may not find another illustration of this in some cases of atrophy of the pigment of the choroid adjacent to a spot at which it is collected, and also in the heaping up of pigment in association with areas of atrophy. But this may have another explanation.

To return to my proper subject. I desire especially to fix in your mind the fact of the occurrence of this characteristic pigmentation. Whether or not you are able to become actually acquainted with its appearance, it may chance to be as useful to you as it was to me this year. Last February a young Indian civil servant, a district magistrate, was brought to me by his family medical attendant. He had just arrived in England with symptoms of extensive peripheral neuritis, so severe that he could not stand or walk without assistance. There was much weakness of the legs as well as wasting of the muscles. There was incoördination and absence of the knee-jerks, considerable fibrillation in the wasted muscles of the thighs, and great diminution in electrical excitability, which also presented a peculiarity with which I need not now trouble you. There was also considerable impairment of sensibility to pain and touch. His hands likewise were weak and very unsteady. The illness had followed a sharp attack of intermittent fever two or three months before, and he had previously suffered badly

from the ordinary malarial fever in India. Such neuritis is well known as an occasional sequel to these malarial fevers, caused apparently by a toxin which is left in the system. But in that form the muscles of the lower legs are chiefly affected and incoördination is seldom a prominent symptom. When I came to examine the patient's body I found it covered with pigmentation perfectly like that of arsenic. Indeed, I could not doubt its nature. Of course, I questioned him carefully regarding any possible source of arsenic-poisoning, and especially whether he had taken any tonic containing arsenic. It seemed certain that he had not, and no accidental source could be ascertained. Thus the sequence of events suggested malarial influences as the cause, but it was impossible to misinterpret the declaration so clearly written on his skin of the influence of arsenic. Moreover, another fact was learned which gave support to the cutaneous message. About the time of the commencement of his illness he had an attack of shingles. It is a long time (35 years) since Mr. Hutchinson pointed out that herpes zoster may be caused by arsenic. Hence we were compelled to consider that his condition was due to this, in part or altogether; the facts were too definite, although inexplicable, and we treated the patient accordingly. Six weeks later the medical attendant wrote to me that the mystery was cleared up. News had been received from India of the discovery of a prolonged attempt to kill the patient and his family by the habitual introduction of arsenic into their food. Several members of the family had suffered severely and the nurse had actually died from the poison. Our patient improved steadily, and I saw him a fortnight ago practically well, able to walk fairly and cycle 30 miles. The ataxy had vanished; some blunting of sensibility on the front half of the soles alone remained. He will soon return to his work in India. What is of particular interest, because it relates to a point about which we know little, is that the arsenical pigmentation has almost disappeared.

Another pertinent instance of the revelation which this sign may afford I need only allude to because I have already described it in a volume of clinical lectures under the heading of "Mistaken Diagnosis." The patient came with what seemed to be characteristic symptoms of ordinary tabes—pains, ataxy, and loss of knee-jerk. He came when I could not properly examine him, so I ordered him some medicine containing arsenic and arranged to see him again in a month. Then when I stripped him to test his sensation, to my consternation I found his skin covered with typical arsenical pigmentation. He was a colour-merchant, accustomed to deal in various pigments, but he had also taken for a long time a tonic pill containing arsenic. Both these cases illustrate the tendency of the sensory nerves to suffer under arsenic far more than under lead. The patient recovered and he taught me another lesson. There is evidence that iodide of potassium promotes the elimination of arsenic as well as of lead. The path by which it can pass away is, of necessity, the blood. You know that it is not well to give iodide freely to a patient with recent and severe lead poisoning because the lead stored in the tissues may be thrown into the blood too suddenly. This case showed that we should be equally cautious in the case of arsenic. Iodide in very moderate doses led to such an increase in the symptoms of irritation of the nerves as to compel its discontinuance for a time and very gradual resumption.

I have only one other instance to mention to you and that is an illustration of the other side of the shield. An epileptic patient, a young woman, about 30 years of age, presented marked pigmentation from the arsenic taken with bromide. From the latter she was deriving great good. I explained the nature of the darkening of the skin and she was satisfied. About six months later I received a letter from her sister written in dire distress. The aspect of the skin had caused two medical men to assure her that the patient was certainly the subject of Addison's disease—a progressive incurable malady. I could only reply that the patient when I last saw her presented darkening of the skin due to the arsenic. I heard no more of the case. It is right to say that this was before the Manchester epidemic had its opportunity of exerting its educational influence on the profession.

The facts I have given you are commonplace. Many of them may have been known to some of you, some of them may have been known to many of you; but one fact I am sure is true of all my hearers—for it is as true of myself as of anyone—the commonplace is of all knowledge that which we can least afford to despise or to disregard.

## An Introductory Address

OR

## HUMAN AND BOVINE TUBERCULOSIS.

*Delivered at the Royal Veterinary College, Camden Town,  
on Oct. 1st, 1901,*

By EDGAR M. CROOKSHANK, M.B. LOND.,

EMERITUS PROFESSOR OF COMPARATIVE PATHOLOGY AND  
BACTERIOLOGY, KING'S COLLEGE, LONDON.

GENTLEMEN,—I esteem it a great honour to have been invited to deliver the introductory address, and it is a sincere pleasure to me as a governor of this college to welcome to-day both new and old students. It is very gratifying to all those who have the interests of this college at heart that the number of students for several years has been so well maintained. I congratulate the new students upon the choice they have made in selecting the veterinary profession as their career in life. I congratulate them also upon the advantages which they will derive as students of this institution. The Royal Veterinary College not only stands in the front rank of veterinary schools in the British Empire, but it compares very favourably with those great institutions in France and Germany which have a world-wide and long-established reputation. In this country great difficulties have to be encountered by those who desire to promote scientific education. There is not the same amount of sympathy and financial support which is given to scientific institutions in America and on the continent. And therefore I feel very strongly that those who are responsible for the management of this college may, considering their limited resources, claim great credit for making the teaching so efficient and for placing opportunities for original research within the reach of both the teaching staff and the students.

With very many parents it is a most difficult matter to choose a career for their sons, and therefore it ought to be more widely known that it is a great advantage for young men to pass through a course of training in a veterinary college. Much might be said with regard to the danger of overcrowding the profession, but I venture to think that there is still plenty of room. The ranks of those engaged in private practice have to be filled up. There is a great demand in the army for thoroughly trained veterinary surgeons. Many members of the profession have rendered splendid services in the great war in South Africa, and if the experience of this war leads to the employment of mounted troops in still greater numbers, if, in other words, horses are destined in future wars to play such a conspicuous part, there must necessarily be a still greater demand for the services of those who have to select and to take charge of them. There is also an increasing demand for veterinary surgeons in the colonies. In South Africa and our other possessions the best methods of stamping-out animal plagues must occupy the attention of the colonial Governments and thus give employment to veterinary surgeons. There must also arise a greater demand at home for their services. The eradication or diminution of such diseases as bovine tuberculosis could only be attempted by the intelligent coöperation of the public with veterinary officers of health.

There are many parents who send their sons to the universities without having definitely settled upon their future career, and many parents who could not aspire to sending their sons to a university would do well to secure the advantages of a scientific education by sending them to a veterinary college. They would receive a sound scientific training, and the fees for the whole curriculum, exclusive of the cost of living, are less than the fees for sending a boy for one year as a boarder to one of the best preparatory schools. If the student did not eventually practise as a veterinary surgeon the time spent in acquiring veterinary knowledge would be by no means lost. Every well-educated man should have some acquaintance with the subjects which are taught at a veterinary college, such as botany, biology, physiology, chemistry, and even anatomy. Anatomy is of special value in training the intellect. It is an exact science, and the mind of the student is not disturbed by new theories and a variety of opinions. It encourages accuracy in

observation, it necessitates an accurate memory, and it trains the hands in delicate operations. As the student passes on to the essentially professional subjects—I mean the recognition, cure, and prevention of the diseases of animals, especially of horses and cattle—it will at once be admitted that there are many occupations in which a knowledge of these subjects can be put to practical account. A student may not ultimately elect to practise; he may prefer to take up farming either at home or in the colonies. He may become an estate agent or be called upon to lead the life of a country gentleman, and perhaps to serve on the "Diseases of Animals Committee" of a county council or other local governing body. In any of these positions the information which he would have received would prove to be of very great advantage.

#### PRELIMINARY EDUCATION.

In the education of students before they come to the college it is very desirable that attention should be given to foreign languages, especially French and German. Foreign veterinary surgeons have a great deal to learn from our methods, and English veterinary surgeons are equally indebted to the work and experience of their foreign colleagues. Some of the best text-books were written by foreign authors, and if the scientific veterinary surgeon in England wishes to keep in touch with continental opinion, experience, and research work it is an enormous advantage to be able to read the original publications. To depend upon the chance of translation or upon meagre abstracts in English is very unsatisfactory, and many contributions to literature would be quite out of reach. Those who held office as advisers to county councils or aspired to appointments in the Veterinary Department of the Board of Agriculture would appreciate the value of being able to study the reports of the agricultural departments of other nations. The admirable reports of our own Board of Agriculture would at a glance illustrate this point. This is, however, not the only value of a knowledge of French and German. International veterinary and science congresses are becoming more and more popular. The opportunities for exchanging opinions and experience with other nations are increasing, and the hard-worked veterinary surgeon might combine with the enjoyment of travelling the opportunity for exchanging ideas with his professional brethren by attending these congresses in foreign countries.

I do not require to be told that the veterinary surgeon has to think first of making a living—I am quite aware of that fact; but it must be remembered that travelling on the continent is a very different matter from what it was 20 years ago. The expenses have been reduced to such an extent by coöperation that an opportunity for foreign travel is placed almost within the reach of all. I would not even leave out the students; I should like to see parents encouraging the idea of "students' coöperative tours," thus enabling them to combine a little sight-seeing and the enjoyment of travelling with a visit to the museums and laboratories and school buildings of such institutions as the great Veterinary School of Alfort, near Paris, the Veterinary School at Berlin, the Pasteur Institute in Paris, and the Hygienic Institute at Berlin, where diseases common to man and to lower animals are constantly the subjects of investigation. Travelling scholarships would be of quite as much advantage to veterinary as to medical students.

#### HIGHER EDUCATION.

I do not propose to discuss the question of the higher education of veterinary students, but I trust that I may be forgiven if I again allude to a subject which I referred to on a similar occasion many years ago—I mean the desirability of conferring a degree in veterinary science. I desire to draw the attention of the leaders of your profession to this question—Why should not the Veterinary College be recognised in the new University of London? I would also again point out what a great advantage it would be both to veterinary surgeons and to the public if the Royal College of Veterinary Surgeons could see their way to instituting a special examination and conferring a Diploma of Preventive Veterinary Medicine. The course of training should be somewhat similar to the course of instruction given to medical men for the Diploma of Public Health. I hope to see the day when every county council and every rural and urban council will appoint a veterinary officer of health, and every applicant for such a post be required to hold the Diploma of Preventive Veterinary Medicine. I hope that in the future more veterinary surgeons will be placed in a position which

will enable them to devote their lives to original research. There is an enormous field for investigation in the causation and prevention of diseases of animals.

#### TUBERCULOSIS.

It would be impossible to give a better illustration of this fact than by referring to tuberculosis in animals, especially cattle. At the recent International Congress in London the relation of bovine tuberculosis to human tuberculosis was prominently brought forward in a paper read by Dr. Koch, and the question is of so much importance that the Government has appointed another Royal Commission to inquire into it. The governors, the staff, and the students of this college are all, I am sure, very proud of the fact that the researches made by your distinguished principal and the great reputation which he has made by his knowledge of comparative pathology have led to his selection as a member of this most important Commission.

It is instructive and encouraging to the veterinary profession to know that the researches which created most interest at the Congress were those undertaken in different veterinary colleges. Dr. Koch's experiments were carried out during the past two years with the coöperation of Professor Schutz in the Veterinary College at Berlin. It is necessary to refer to these researches in some detail to explain the point at issue and to compare the work and conclusions of Dr. Koch with the experiments and opinions of others who have investigated this subject. Dr. Koch in various ways inoculated 19 cattle with human tuberculous virus and none of them showed any symptoms of disease. On the other hand, cattle inoculated with bovine tuberculosis suffered, without exception, the severest tuberculous disorders of the internal organs. Dr. Koch concluded that human tuberculosis differed from bovine and could not be transmitted to cattle, and he further announced that whether man was susceptible to bovine tuberculosis at all was not yet absolutely decided, and that if such susceptibility really existed the infection of human beings was but a very rare occurrence. Dr. Koch believed that the extent of the infection by the milk and meat of tuberculous cattle and the butter made of their milk was hardly greater than that of hereditary transmission, and therefore he did not deem it advisable to take any measures against it. I must express myself in full agreement with Dr. Koch that if infection occurs at all it is of very rare occurrence, but I entirely disagree with the statement that human tuberculosis cannot be inoculated in cattle, and I must add that I consider Dr. Koch's statement with regard to preventive measures as singularly unfortunate. It conveys the impression, as pointed out by Dr. Hueppe, that Dr. Koch would have us concede to dairymen and milk-sellers the right of selling tuberculous milk. I feel justified in disagreeing with Dr. Koch on these points because in the course of an inquiry on "Tuberculosis in Relation to the Public Milk-supply" which was published in the report of the Board of Agriculture for 1888 I made the following experiment. A perfectly healthy calf was inoculated intra-peritoneally with very virulent human tuberculous sputum and the result was extensive tuberculous deposit at the point of inoculation with hundreds of tuberculous new growths extending from it. The calf died from blood-poisoning 42 days after inoculation and sufficient time had elapsed for the most pronounced infection of the peritoneal cavity. On microscopical examination extremely minute tubercles were found disseminated throughout the lungs and liver. Long and beaded bacilli of the human type were found in these organs and in the peritoneal deposits. This experiment was also made in a veterinary college. It was made in the institution in which we meet to-day, thanks to the great interest taken in the investigation by your former Principal, Sir George Brown. There was no need for me to repeat this experiment as it was absolutely conclusive, and it does not require any Royal Commission to verify the result. Other investigators in England and America have already confirmed this experiment. Dr. Sidney Martin, in experiments on behalf of the Royal Commission on Tuberculosis, succeeded in infecting cattle with human tuberculous virus. In Experiment 1 four calves received with their food sputum from two cases of pulmonary tuberculosis in man. One calf killed in about four weeks showed 53 nodules of tubercle in the small intestine; the second, killed in eight weeks, showed 63 nodules; the third, killed in about 12 weeks, showed 13 nodules; and in the fourth calf there were no nodules

at all. In Calf 3 the nodules in the intestine contained tubercle bacilli. They were absent in the microscopical specimens made of the nodules in Calf 1 and Calf 2, but Dr. Martin pointed out that these nodules were tuberculous although no bacilli were found. In Experiment 2 two calves received at one feeding tuberculous sputum. In one calf killed in eight weeks there were 13 tuberculous nodules in the small intestine and tuberculosis of the mesenteric glands. Tubercle bacilli were found in both sets of lesions. The second calf, killed in about 19 weeks, showed no disease.

Dr. Ravenel, of the Veterinary Department of the University of Pennsylvania, has recently carried out experiments of an equally positive character which he made known at the British Congress on Tuberculosis in London. Four calves were, as in my experiment, inoculated intra-peritoneally with tuberculous sputum. In one case the result was negative, in the other three a post-mortem examination showed that all had become infected with tuberculosis, the lesions in two being quite extensive. On the other hand, calves fed on human tuberculous sputum showed no trace of the disease when they were killed for examination. It is not impossible to explain these contradictory results; they are quite in harmony with the view which I hold that human and bovine tuberculosis are distinct varieties of the same disease. Man is not the natural soil of bovine tuberculosis. The attempts to transmit human tubercle to cattle would not be uniformly successful, and experiments which did not entail the direct insertion of the virus into the tissues might fail entirely. It is quite possible that in my successful experimental case the simultaneous production of blood-poisoning diminished the natural resistance of the tissues and rendered the animal markedly susceptible to infection with the virus from a foreign soil. The difference which may exist in the nature of the soil upon which a virus is inoculated must always be remembered. It is well illustrated by the result obtained by the inoculation of human small-pox upon cattle. Cattle do not naturally suffer from small-pox, which is essentially a disease of man, but it can be grafted on bovine tissues in exceptional cases. These experiments are so difficult that many experimenters who have failed have refused to believe in the positive results obtained by others. But variolation of the cow is nevertheless possible, and so marked is the effect of the soil that the highly infectious small-pox of man is transformed into a locally-inoculable, mild, vesicular malady in cattle, and can never again acquire an infectious character. Sheep-pox may be given as another instance. In this case a highly infectious malady in sheep when successfully grafted on human tissues is deprived of its infectious character and reduced to the condition of a mild vesicular disorder.

All tubercle bacilli can be inhaled and taken with food by perfectly healthy individuals without producing tuberculosis, but if from any predisposing cause there is vulnerability of the tissues it is reasonable to be suspicious of bovine bacilli. As human tuberculous virus can be grafted on to the cow, so also there are cases in which bovine bacilli invade the human tissues. I refer to those cases in which there has been direct inoculation of man. Cooks, grooms, and butchers may suffer from tuberculous nodules in the skin containing tubercle bacilli, but they undergo caseation and disappear. I agree with Dr. Koch in the opinion that human infection can only be quite exceptional. If it were not so, owing to the frequency with which tubercle bacilli occur in milk, cream, butter, cheese, and the quantity of meat derived from tuberculous cows, the inhabitants of every country in the world in which bovine tuberculosis was prevalent must necessarily have been decimated by tuberculous disease. I do not accept the theory that abdominal tuberculosis in children is due to infection from tuberculous milk. Those who advocate this view would appear to set aside the opportunities for infection from a human source. If tubercle in children is the result of infection of the digestive tract there are plenty of opportunities for self-infection when there is concurrent disease of the lungs and there are obviously many ways by which a child might be infected by the mouth with bacilli from a human source. Physicians who have had enormous experience with tuberculous patients of all ages are by no means ready to attribute consumption in any form to tuberculous milk or meat. Sir R. Douglas Powell in his evidence before the Royal Commission when asked if any danger existed in consuming meat bought in the butcher's shop or in using milk

from the milk-pail—i.e., whether the consumption of milk and meat from tuberculous animals might cause the disease in man—replied that he had not met with any cases in his experience which would connect the two facts together. Dr. J. F. Goodhart, consulting physician to the Evelina Hospital for Children, gave similar evidence. I am convinced that any suspicion of danger can be removed without creating a public scare. It is simply a question of better inspection of dairies and any risk which may exist can be met by adopting the precaution in both private and public dairies of destroying "wasters" or "piners" and removing all cows suffering from any disease of the udder. There is no necessity to insist on the boiling of all milk. Unless there are urgent reasons it is not a practice likely to be generally adopted. Boiled milk is very unpalatable to many people and the boiling of milk alters its composition and renders it, in the opinion of many, a danger to infants. Sir R. Douglas Powell and Dr. Goodhart were not prepared to recommend the boiling of milk as a precaution against tuberculosis. Tuberculosis of the bowels is almost unknown in very young children, and it is not very common even in children of from five to 10 years of age. In Dr. Goodhart's experience cases occurring in children with a distinct family history of tubercle were very widely spread, and it was quite common to find children becoming tuberculous after measles, bronchial pneumonia, whooping-cough, and intestinal catarrh.

As regards any danger from tuberculous meat it is, in my opinion, practically *nil*. I do not believe that there has been a single case recorded of tuberculosis contracted by eating tuberculous meat. Jews have a very thorough system of meat inspection and yet they are by no means free from tuberculosis. When travelling in the West Indies I found that tuberculosis was by no means uncommon among negroes, and Dr. A. D. Williams of Demerara stated before the Commission that Hindoos and negroes suffered severely. Dr. Williams said that the Hindoos eat very little meat of any kind. The negroes also eat meat in very small quantities, either salt beef or salt pork imported from America, and this is well cooked before it is eaten. They lived for the most part in small and badly-ventilated buildings. Negro children suffered from tubercle. They did not have as much milk as they ought, and usually, owing to the climate, the milk was boiled.

I think that we are justified in concluding that if the carcass is well nourished the meat is perfectly wholesome in spite of the existence of local deposits of tubercle in the organs and glands, which should of course be condemned. The view that an animal in prime condition but with a minute tuberculous nodule was a diseased animal and that the carcass ought therefore to be destroyed was a very extreme view and could not be carried into practice. As a matter of fact, there could be no justification for wholesale destruction of such valuable food. Compulsory destruction of every animal with a tuberculous deposit would almost involve the ruin of the agricultural industry, and it would be quite inconsistent with the continued use of meat imported from countries where such drastic measures were not entertained. No Government would face the question of compensation for every case of tuberculosis, however slight the lesion. It would be quite as reasonable to demand the destruction of the carcass of every animal suffering from an actinomycotic tumour. Actinomycosis is not only prevalent in cattle, but, like tuberculosis, it is also a disease of the human subject. In this country, in America, and in Australia it is still commonly known as "cancer." Cancer of the tongue, cancer of the jaw, cancerous polypus, and cancerous sores are different manifestations of actinomycosis. Quite recently a correspondent in the *Times* has suggested that eating the flesh of such animals may account for the prevalence of cancer in man—a most fallacious suggestion, for actinomycosis and cancer have nothing in common except the popular and misleading designation. It was at one time thought, as in the case of tuberculosis, that the disease in man is derived from cattle, and I have succeeded in grafting the human disease in a calf. They are, however, in my opinion, distinct varieties and I do not accept the theory that men and animals infect each other, but I believe they contract the disease quite independently and that the micro-organism is probably derived from cereals. Does the tubercle bacillus, like the streptothrix actinomyces, exist outside the animal body? There are many other questions bearing on the life-history of the tubercle bacillus, its exact rôle in tuberculosis, and its relation to other organisms which are closely allied to it

both as regards morphology, staining reaction, and cultivation, such as the bacillus of avian tuberculosis, the tubercle bacilli obtained from fish and worms, the bacillus of Rabinowitsch from gangrene of the lung, of Marpmann from urine, of Mironescu from human faeces, of Karlinski from nasal secretion, of Rabinowitsch from milk and butter, and of Møller from timothy-grass and the dust of other grasses. It is to be hoped that incidentally the new Royal Commission will throw some light on these points.

To eradicate tuberculosis in cattle and so to ensure the breeding of perfectly healthy stock, and thus to restore the confidence of the public in the supply of wholesome meat and milk, will be a splendid work for veterinary surgeons to undertake and one to which they must direct all their energies. As regards the prevention of tuberculosis in man that must be left principally to the sanitary inspector and the medical officer of health. We must not concentrate all our energies upon the destruction of tubercle bacilli but rather give more attention to other factors responsible for the causation of tuberculosis. The study of tuberculosis in animals may throw some light on these causes, and experience of the disease in man may assist in elucidating the causes of disease in animals. Tuberculosis is peculiarly liable to occur among birds and animals kept in captivity. Poultry and guinea-fowls are often the subjects of this disease, and ostriches and other birds in the Zoological Gardens become infected. In monkeys in captivity the disease occasionally occurs in an epidemic form. Pheasants in preserves are attacked sometimes in large numbers and rabbits in overcrowded warrens. These instances help to illustrate the view that damp and other insanitary conditions, confinement, overcrowding, defective ventilation, heredity, and breeding in and in were the most powerful factors in rendering the tissues prone to tubercle and a fitting soil for the invasion of the bacilli. We must not omit in the case of man the influence of alcoholism which has been so closely investigated by Dr. Brouardel; the influence of previous illnesses, such as measles and whooping-cough, as urged by Dr. Goodhart; and, lastly, the influence of special trade occupations which involve inhalation of dust of various kinds.

There are two points which I will discuss at greater length—heredity and tuberculosis in children. Heredity is of two kinds: there is hereditary predisposition to the disease and hereditary transmission of the virus. There is an inherited susceptibility or weakness which renders many individuals liable to the development of tuberculous disease. Family history plays a very important part in human tuberculosis. Sir R. Douglas Powell states from his experience that 48 per cent. of the cases in hospital suffering from tuberculosis had a previous history of hereditary tuberculosis. Whether all these cases are cases of hereditary predisposition, or hereditary transmission of the virus, or examples of both, is not determined. I am entirely in agreement with Dr. Klein and Mr. Victor Horsley that in some cases there is direct transmission of the virus and that it may exist for many years in a latent form. Dr. Klein brought this matter very convincingly before the Royal Commission. In connexion with this question of heredity some interesting observations upon tuberculosis in birds have been recorded by Dr. Baumgarten. On a poultry farm a cock developed tuberculosis. All the chickens reared from this cock were tuberculous. There was no evidence that the fowls were infected with either human or bovine tuberculous virus. An identical case occurred on another farm, and these cases have been accepted as evidence of the direct transmission of the virus from the parent bird. Tuberculosis is a rare disease in calves. It seems probable that those cases which do occasionally occur are mostly, if not entirely, the result of hereditary transmission. In discussing the occurrence of tuberculosis in children we may derive some consolation from the immunity of calves. Tuberculosis in children is largely a disease of the poor. It attacks all classes but is extremely common among the London poor and the poor of our overcrowded cities. I would attribute the disease in children to a want of milk rather than the possible occurrence of a few stray bovine bacilli in milk. Plenty of milk, good nourishing food, and better hygienic surroundings will do more to diminish the numbers of tuberculous children than any legislation directed against bovine bacilli. In proportion as the slums are removed from our overcrowded cities and the problem of the better housing of the poor has been solved we may expect to see a steady diminution in the amount of tuberculosis in children. I believe

that the infectious nature of the disease has been exaggerated. It is quite possible that the theory is fallacious—I mean the idea that phthisis can be caught like scarlet fever or may be compared to typhoid fever is, I think, a mistake. In typhoid fever epidemics at home, in India, and in South Africa we know that apart from cases of individual insusceptibility we have not to consider any other factors except the introduction of the specific poison of typhoid fever. Those in health and out of health fall victims to the disease if they have taken the poison in water or in food. There is no question at all of hereditary transmission or of predisposing conditions which render the subject susceptible to the poison. At the same time the habit of spitting in public places and railway carriages and other conveyances should be prohibited, and the sputum of phthisical persons should be disinfected. Several years ago I carried out experiments proving that sputum treated with 20 per cent. carbolic acid was rendered quite inert. Guinea-pigs inoculated with the carbolised sputum remained perfectly healthy and all control animals were infected without exception. There is no need to create a panic or raise an outcry for legislation to make spitting in public places a matter to be dealt with in the police-court. That the virus of tubercle scattered far and wide becomes a constant source of danger to all who inhale the air is not a theory which is supported by experiment and experience. Dr. A. Ransome maintains that in a well-ventilated room it is rendered harmless. Tuberculous sputum was exposed in the ventilating shaft of a hospital and proved virulent to rodents, but similar sputum exposed for the same time in Dr. Ransome's room, which was ventilated and well lighted, was absolutely harmless. Dr. Klein placed a number of guinea-pigs in cages in the ventilating shaft of the Brompton Hospital very many years ago. They were kept there for several weeks and all of them became tuberculous. We must not too hastily draw conclusions from experiments upon small animals such as rodents. In the same institution it was found among all those who had been connected with it—nurses, porters, physicians, surgeons, and so on—that the mortality from consumption was quite within the average of ordinary mortality. I am convinced that if tuberculosis were readily conveyed from person to person that marriage of individuals who become or are consumptive would be a fruitful source of direct infection. We should hear constantly of instances in which married people had infected each other with tuberculosis owing to the opportunities which occur for conveying the disease by the breath and in other ways. It is necessary to lay great stress upon the difference between experimental inoculation and natural infection. I cannot therefore regard tuberculosis as catching in the same sense that scarlet fever is catching, nor can I regard the comparison to typhoid fever as one that is not very misleading.

Those who aim at eliminating the conditions which I have referred to as powerful factors in the production of tuberculosis will render the greatest services in the crusade against tuberculosis in animals as well as in man.

**THE VEGETARIAN SOCIETY.**—The fifty-fourth annual conference of the Vegetarian Society was held in Manchester on Oct. 21st. At the morning meeting papers were read on various aspects of their subject. Mr. Alfred Russell considered "Vegetarianism and the Humane Spirit." Mr. Albert Broadbent stated that there was scarcely any toothache or neuralgia where whole-meal bread was used and dealt with the investigations of Mr. T. G. Read of the British Dental Association into the decay of teeth, which was said to result from the grinding of flour in roller mills. The public meeting in the evening was presided over by Mr. F. Eustace Miles who on a vegetarian diet said he could keep up training and brain work without regular exercise. The enemies of vegetarianism he considered "included the advocates of the slow-eating diet, no breakfasts, physical culture, and others." The advocates of vegetarianism "should insist on three aspects—the humane, the æsthetic, and the economic." With regard to the first two aspects Mr. J. C. Street said that the vegetarian diet gave "a spiritual clearness of vision that could not be obtained in any other way." The system does not appear to make rapid headway, for after 53 years of existence the society only received 11 associates and 48 members during the last year. It was stated that "a large number of distinguished and valued friends in the vegetarian world had died during the year." With all the claims made for vegetarianism this is surely unusual.

ABSTRACT OF A  
**Presidential Address**  
 ON  
**VENTILATION.**

*Delivered at the Annual Meeting of the Incorporated Society  
 of Medical Officers of Health on Oct. 25th, 1901.*

By A. WYNTER BLYTH, M.R.C.S. ENG.,  
 F.C.S., F.I.C.,

BARRISTER-AT-LAW; MEDICAL OFFICER OF HEALTH OF THE METRO-  
 POLITAN BOROUGH OF ST. MARYLEBONE.

[AFTER saying that he would define ventilation as being not the mere mingling and wafting of aerial mixtures, but the continuous replacement of air more or less vitiated of inhabited rooms or workshops with the purest air attainable, Mr. Wynter Blyth proceeded:]

Unpolluted water-supplies, the prompt removal of all kinds of dirt, excretal or otherwise, and abundance of suitable healthy food are common blessings of civilised communities; but the air of bed-chamber, of dormitory, of living-room, of factory, of workshop, and of meeting-place continues to produce that low state of health which conduces to the spread of tuberculous and other maladies. In these latter days it has come as a revelation and surprise to many that not a drug in the Pharmacopœia, not an animal extract, not one physical appliance with which science has enriched the remedial art, either singly or collectively, is equal in the treatment of tubercle to bathing the lungs and skin in fresh air. The remarkably successful treatment by open air of consumptive maladies must suggest to us, the guardians of the public health, that if air is curative it is also preventive, and that if abundance of pure air can be supplied to each unit of the population the death-roll from phthisis will be so insignificant as to render special sanatoria unnecessary. The problem to be solved is not the changing of air three times an hour in the spacious rooms of the well-to-do, or in large public rooms, or in hospitals, but in the quite small cubes sanctioned by the legislature—spaces of 400 and 300, or even of 250, cubic feet—for, obviously, if the problem is solved for the smaller it is also for the larger space. As the air in the streets of our towns not infrequently contains as much as six parts per 10,000 of carbon dioxide, it follows that this figure cannot be accepted as the standard of impurity for rooms of houses. A preferable standard would be two parts per 10,000 in excess of the outside air.

There are two distinct advances in the theory and practice of ventilation which have been made recently: the one is the publication by the Sanitary Institute of the report of the Cowl Committee; the other is the wide distribution of electric energy, permitting such mechanical appliances as rotating fans to be utilised by ordinary householders. Wherever there is an electric supply mechanical ventilation is cheap and practicable. The work of the Cowl Committee has extended over 25 years and has embraced a large number of experiments with cowls and ventilating shafts under numerous conditions. The results arrived at are, first, that anemometers vary considerably in the information which they record, according to the situations in which they are employed. The same instrument will give an entirely fallacious reading when used in a confined tube, if it has been standardised in a fairly open space. Thus, it was found necessary to standardise the instrument used by placing it in a tube of similar diameter to that in which it was proposed to use it and by passing a known quantity of air through the tube. Secondly, that a properly designed cowl or terminal gives a much better result than an open pipe of the same height and dimensions. As the flow up the pipe depends upon the head and the resistance (the flow being equal to the square root of the ratio of the head to the resistance), it follows that when the outside air is still the head will be so reduced in amount that there will be no appreciable flow of air up the tube. It is evident that when ventilation is wanted least—that is, in time of high winds—the shaft is most efficient; whereas on dull airless days, when ventilation is most required, the shaft is least efficient.

[Mr. Wynter Blyth condemned many forms of window appliances and even some forms of Tobin's tubes as being unsatisfactory from the disagreeable shower of cold air to

which inmates of rooms so fitted were subjected. Tobin's tubes were, however, capable of improvement and might be placed in such positions as would prevent any person's head being exposed to the downpouring cold air. Satisfactory results were to be obtained by the use of ventilating grates, especially in winter, when a large body of comfortably-warmed air might be cheaply supplied. The current in its passage caused a variety of eddies and currents and mixed up the air of a room in such a way as to make its composition more uniform. Mr. Wynter Blyth then detailed a number of experiments which he had made to show how important it was to have inlets and outlets properly placed. He continued:]

If, for example, the inlet be placed on the same level with an outlet the air may blow right across without affecting the main body of air in the room. The generally received doctrine of placing inlets for natural ventilation some four or five feet high, with openings towards the ceiling and outlets near the ceiling or at the ceiling, is in the main correct, but where there is excessive floor pollution, as in the day wards of idiot asylums, if mechanical ventilation is employed and warm air is driven in then it is best to make large openings on a level with the floor and so sweep away offensive odours. Even with natural ventilation it is certainly useful in such cases to have openings on a level with the floor, closed at will, so as to allow fresh air to stream freely over the surface. The great principle in ventilation is to remove polluted air as quickly as practicable, and that is best done by having the exit openings as close as possible to the localities where the air is polluted. Such a position chosen systematically is not possible with natural ventilation; it is only possible with mechanical ventilation.

#### MECHANICAL VENTILATION.

Whenever it becomes a question of difficult ventilation, such as in mines and underground places, it is the practice to use some form of mechanical ventilation, and, as already mentioned, the spaces for habitable rooms and working places sanctioned by law are so small and inadequate for the purposes of health that ordinary ventilating appliances dependent on the action of so-called natural ventilation do not effect their object. There are many forms of mechanical means of producing a "head," as, for example, by steam or water-jets, by punkahs, by large machines of the bellows type, and so forth, but the only form applicable generally is by means of rotating fans. Mechanical ventilation is almost synonymous with ventilation by the aid of fans, although not entirely. The applications of fans are numerous and important. A fan may be used to drive soot-free and dirt-free air through filtering media into inhabited rooms on foggy days, or it may extract smoky or offensive air from such places as smoking-rooms or lavatories. Fans have been applied for quite a century in certain trades to blow or suck away noxious dusts, or to similarly deal with injurious gases. In principle all the fans are identical. A number of vanes are attached to an axle. When the fan rotates the particles of air slip along the vanes on the tips, and leave the tips at a tangent with almost the velocity of the tips themselves. There is, therefore, a motion of air from the centre to the periphery and a diminution of pressure at the centre or axis. During hot summers electric fans may be seen rotating rapidly in many shops in the metropolis on the counter and worked from the ordinary electric supply. Applied in this way the air leaves the wheel at all points of the periphery tangentially and merely aids the local circulation. To obtain the full effect such a fan must be inclosed in a circular cover with openings at the axle and a tubular aperture at the periphery. In this way delivery may be made to take place along the tube. In the near future, without doubt, the cost will be much reduced, as there is a tendency to cheapen generally the transmission of current as the processes for the production and transmission of electrical energy become perfected. Nor is the motive power applicable to the moving of a fan restricted to the electric current. Advantage in large lavatories, and in places where there is abundance of water running to waste, has been taken of the flow of water. In factories where steam-power is available fans may be run at a cost scarcely appreciable. It is possible, also, that such a cheap agency as petrol, already so extensively employed to propel motors, could be applied in private houses to drive fans.

#### VENTILATION OF SEWERS BY MEANS OF FANS.

Hitherto the ventilation of sewers, whether by open gratings, or by shafts, or by lamp-columns, has been unsatisfactory. What are sewers but a network of miniatur-

mine galleries? Mines may and are ventilated perfectly by mechanical means, and I have the utmost confidence that the problem of sewer ventilation is capable of being solved by a suitable arrangement of fans driven by electric or other power. It was therefore with some considerable interest that with the assistance of Mr. Meredith Wynter Blyth an investigation was made of a small experimental plant laid down in West Ham by Messrs. Aldous of Forest Gate. Here a 12-inch fan electrically driven (1400 revolutions per minute) sucks the foul gases from a network of two miles of 12- and 15-inch sewers at the rate of 14,400 cubic feet per hour. Observations were made at a manhole 550 feet from the fan and at another manhole 1300 feet from the fan. The sewers in each case were about half full. The air in both sewers was so excessively foul as to be nearly irrespirable before the fan was allowed to run. The temperature in both sewers was 59° F., the outside air being 56·3°. There was insufficient air-current to move the vanes of an air-meter. Every few yards along these sewers there are open ventilators in the centre of the roadway; in each of these there appeared to be a feeble up-current. Samples of the sewer air were taken and the carbon dioxide was found to be a little over 19 per 10,000. The fan was now allowed to run nearly an hour and the two sewers were again examined. Although the fan was running at full speed there was again insufficient current to move an anemometer; but the odour, still strong, was certainly somewhat less; the temperature in each case was lower, showing that cool air had been sucked in, and the carbon dioxide had sunk in the one case to about 16 and in the other to 18·5. These results were quite as good as could under the circumstances be expected. To plant a fan down, as in this instance, in the centre of a network of sewers without closing up a single ventilator is to court failure. If sewers are to be ventilated by fans the best results will be obtained by using more than one fan; there should be mechanical contrivances for driving the air in and also for extracting the air, but more than all the area to be ventilated should be carefully prepared by stopping all ventilating shafts save those that deliver to or exhaust air from the sewers. Besides which resistances should be in certain places interposed where either ventilation was but little required or where the current was flowing at the expense of other pipes where the current was too weak. In short, the whole thing requires to be carefully engineered. Nevertheless, the installation amply proves that fan ventilation of sewers is practicable, that even such a crude installation exercises an appreciable effect on the sewer air, and there is no reason to believe that it would be too expensive. In cases, indeed, where the local authority owned an electric plant the maintenance of a few fans in certain portions of the sewer system could not be a serious matter.

#### VENTILATION OF THE CENTRAL LONDON RAILWAY.

An example of mechanical ventilation with which everyone must be familiar is afforded by the Central London or Tube Railway. The railway consists of two tubes, for the most part parallel to each other, 10,163 yards in length, 11 feet 6 inches in diameter, from Shepherd's Bush to the Bank. There are 13 stations, each station being constructed of cast-iron tubes 21·5 feet in diameter and 325 feet in length, one such enlarged tube being for the up and the other for the down line. Considering that the whole of the line and the stations are built up of iron pipes embedded in the clay at a depth of from 60 to 90 feet all the air must be renewed from the upper surface of the ground, hence the conditions are quite similar to that of the gallery of a mine with various shafts along its course. The trains fit the tunnels fairly closely; at the sides there is only an interval of a foot, the top of the carriage is but eight inches from the top of the tunnel, while the bottom stands two feet from the roadway. Owing to this arrangement the tubes practically consist of two large air-pumps, the trains being so many pistons, the one set of pistons moving in one direction, the other set in the opposite direction.

[Mr. Wynter Blyth and Mr. M. Wynter Blyth had made a series of observations on the ventilation of the tubes. Some of the experiments were made at Bond-street Station which stands about midway between the termini, others were made at Notting-hill-gate Station. The velocity of the moving air was measured by an air-meter in the centre of either the up or the down platform. Observations were also taken in the passages leading upwards to the street. The atmospheric pressure, the temperature as measured by the wet and dry thermometer, were also observed. The carbon

dioxide of the air was estimated in the station, on the staircase, in the lift, and in the street outside the station. Mr. Wynter Blyth said:]

With regard to the general movement of air we established the following facts. In front of each train there was a distinct and measurable increase of barometric pressure, in the rear a diminution of pressure. As each train left a station it pushed a column of air in front of it, part of which, on reaching the station, rushed up the staircase into the open air, and as the train left the station air rushed down the staircase from the street. The upward and downward velocities varied with the position of the trains; the latter current was slower than the former and was generally under four miles an hour, while the former on one occasion, when two trains were entering the station almost simultaneously, reached a velocity of 7·4 miles per hour. The maximum velocity in the middle of the platform due to an approaching train was found to be 5·79 miles per hour. The temperature outside for the time of year was low—56° F.—the temperature of the air within was 67°. The difference of temperature is due to several causes—the temperature of the earth-crust retaining the summer heat; therefore, the walls of the tube being warmer than the external air, the animal temperature imparted by the thousands of persons, each at 98°, going backwards and forwards, and some portion may be due to dynamical heating of the air, for it is well known that whenever air is compressed heat is liberated. The amount of carbon dioxide at Bond-street Station was 10·3 parts per 10,000, while on the stairs leading from the station it was a point or two less according to whether the draught was up or down. This compares favourably with a sample of air taken in the tunnel between Gower-street and King's-cross Stations of the Metropolitan Railway, which has 25·9 parts of carbonic dioxide, and even with the council chamber of St. Marylebone Town Hall, where half an hour after a meeting of 56 persons had begun 14·9 parts of carbon dioxide were found present, the amount in the external air in each instance being a little over four parts. In the tube between stations the amount rose to 11·9. At Notting-hill-gate Station the tubes are not parallel, but one crosses the other, and it was discovered that while there were 10·7 parts in the upper station there were only 6·9 parts in the sub-station. The reason of this is that instead of depending upon the movement of the trains to effect ventilation the air is renewed here by means of a powerful fan. The air-supply circulates from the surface of the ground into a circular chamber deep down below the lifts, and up again, by means of downcast and upcast flues. The air rushes down at a velocity of 9·7 miles an hour, giving an hourly air-supply of no less than 855,000 cubic feet. The research clearly shows that where the ventilation depends entirely on the passage of the trains, although there is so much movement of air, so much sucking in from above and blowing out from below, a good portion of the air must be driven backwards and forwards unchanged in the tubes; in other words, the tunnel air is diluted, but the whole of it is never swept out, whereas with the assistance of a fan the ventilation was extremely good.

#### THE VENTILATION OF DWELLING-HOUSES AND WORK-PLACES.

For about nine months in the year houses may be well ventilated by open windows and doors, but in the colder weather it is important to keep the hall, the corridors, and passages, by special warming appliances, at a comfortable temperature; for when windows are fast shut it is through the passages, staircases, and corridors that we obtain most of the breathing air. Hence the necessity, if we wish to avoid unpleasant cold draughts, to keep these conduits warm; then, on the return of warmer weather, the condensation on the walls of moisture is avoided and the house continues dry. In such houses it is better to deal with the rooms individually and give them their own ventilating system. The best method of ventilating an ordinary room is a good warm air-grate with an electric fan, which can be put in action when required so as to draw the air more rapidly from the back of the grate. Such a fan may be easily made with a cover and tube, so that it can be adjusted over the opening and connected by a plug to the ordinary electric-supply. When not required it is easily removeable; when there are an unusual number of people in the room, or from any cause the room is likely to be badly ventilated, the fan can be put in action.

With regard to the ordinary tenement house it is doubtless at the present time hopeless to suggest any mechanical

appliance. The great and essential thing is to consider the passages and staircase; it is when the house is shut up for the night that the great harm from bad air is caused. On every floor—probably in most of the grates on every floor—burns a fire, each chimney shaft is drawing up air from the closed house; the consequence is that the upper rooms particularly are fed from the basement and from various occupied rooms. An ordinary crowded tenement house when you enter in the morning reeks from top to bottom with the peculiar organic odour of the breath of persons. Much of this is obviated if the passages and staircases are well ventilated, and here is opportunity for the use of good upcast ventilators in the shape of cowls; skylights and windows will certainly be closed by the tenants, but a good cowl in the roof, difficult to get at, is the best palliative.

The cubic spaces sanctioned by statute in common lodging-houses, in the cubicles of shelters, in tenement houses, in schools, in factories and workshops, are impossible to ventilate by ordinary means so as to attain even a reasonable standard of purity, and with the growing price of land it is unlikely that the allowance of cubic space per head will be increased. We are therefore bound to consider seriously the question of mechanical ventilation. If some of the great expert talent now employed in the investigation and discussion of problems relating to sewage and sewage disposal was diverted to the studying of systems by which spaces of from 250 to 400 cubic feet could be kept supplied with fresh, pure, pleasant air, our factories and workshops would put out more work in a given time, and the mean duration of human life in this country would be appreciably lengthened. As the deepest mine can be made not only habitable but agreeable and healthy, it should not be impossible to make a subterranean set of offices, lit by the electric light, artificially ventilated, and warmed by the retained heat of the earth, far healthier to work in than many a city office is under present conditions.

## MILK OR WHEY IN ENTERIC FEVER?

By PRIDEAUX SELBY, M.R.C.S. ENG., L.R.C.P. LOND.

THE object of this paper is to condemn milk entirely as a food for enteric fever cases and to point out an efficient substitute in the form of whey.

In the treatment of this disease, more perhaps than in any other, we have a vast field to work upon in the reduction of the death-rate, a field in which I trust to prove that we can work with a good amount of success. The fact that the cold bath treatment of enteric fever has reduced the death-rate in places where it has been systematically carried out to one-half what it was before proves that enteric fever is a disease which has had in the past a death-rate which was unnecessarily high. This death-rate has continued high in spite of the almost measureless improvements in hospital accommodation, in spite of improvements in sanitation, in spite of the system of modern nursing by which our methods of treatment are carried out to the letter, and in spite of the enormous increase in our knowledge of the pathology of the disease.

Bacteriology, again, has taught us more than pathology, but it has taught us the science of the disease and we are inclined to be led away from the old-fashioned methods of treating disease by diet and medicine into methods which can be summarised as antitoxin methods: methods which, though magnificent in diphtheria, in the case of enteric fever are in their infancy, and in their results up to the present time anything but satisfactory.

Forty years ago Murchison gave the average mortality of enteric fever in the London Fever Hospital for a period of 23 years as 16.79 per cent., but in 1855 it was only 14.2 per cent., whilst in 1860 it was 28.7 per cent. Last year the death-rate in the London fever hospitals of the Metropolitan Asylums Board was 15 per cent.; in the British army in the United Kingdom from 1889 to 1898 it was 19.16; and in Charing-cross Hospital from 1890 to 1898 it was 18.5. The death-rate for the quarter ending March 30th, 1901, from enteric fever in the hundred chief towns of England and

Wales was approximately 20 per cent. The death-rate of London for the same period was 18.3 per cent., there being 729 notifications and 134 deaths. That this is so is wrong, radically wrong.

Authorities can be quoted by the dozen who with the intense conservatism which is born in us have continued and still advise a treatment which has been tested for over 50 years and has been proved to be inefficient—that is, the routine feeding of enteric fever cases on milk.

Enteric fever, which, we all know, is synonymous with typhoid fever, though it is difficult to persuade the public of that fact, is a disease which we may divide into two parts—firstly, the bacillus typhosus, and secondly the fever. Concerning the first, the bacillus typhosus is a microbe which is taken into the intestine with food or drink. It breeds in the contents of the intestines and attacks certain definite parts of the intestine, producing a condition which leads to the formation of ulcers. Apparently the bacillus only has the power of attacking the glands called Peyer's patches and has not the power of causing ulceration where there are no such glands. It is from these ulcers which are formed by the sloughing of the Peyer's patches that the chief dangers of the disease arise. The second division of the disease is the fever which is due to the absorption into the circulation of toxins and toxalbumins, which are poisons produced in the intestine by the decomposition of the nitrogenous foods in the form of proteids and albumins—chiefly milk curd. For clinical purposes we may ignore the fact of the bacteria being found in the mesenteric glands, spleen, and kidneys, for they seldom give rise to any local symptoms beyond some enlargement of those organs and do not require any special treatment. The cold-bath treatment has lessened the death-rate by preventing the high temperatures and their concomitant evils, but it must be a more sound form of treatment to go to the root of the evil and to lessen the production of these pyogenic poisons.

Milk should not be given as a diet to enteric fever patients, firstly, because milk in many cases forms hard cheesy curds in the stomach. These curds pass along the intestine, giving pain and scraping the raw surfaces of the ulcers and causing in many cases hæmorrhage, perforation, and death. The effect of these cheese-like masses of casein is worse for the patient than feeding on well-masticated solids. Moreover, the perpetual distension of the bowel from the large amount of gases evolved by the digestion or decomposition of the milk keeps the ulcers stretched and thus thins their floors. Secondly, because the bacillus typhosus breeds rapidly in milk, the more bacteria there are the more the toxins produced, and the more the toxins the more the fever and constitutional disturbance, with foul mouth, headache, cardiac weakness, delirium, and a feeling of illness.

In passing I would say that it would be a point of great interest for bacteriologists to determine whether the bacillus typhosus can live and increase in a medium containing no nitrogen, either in the free state as in air or in combination as in nitrogenous foods. I can find no record of any such researches. Though it breeds in water there is generally free nitrogen present in the form of air.

Now for the remedy. If we do not give milk what can we give in its place?

In a paper on typhoid fever which I read before the East Kent Branch of the British Medical Association at Canterbury I bemoaned the physiological necessity for milk as a diet and appealed to the members present to suggest a substitute, for I was convinced that it was wrong to give it. One gentleman, whose name it is my misfortune to have forgotten, mentioned that he had heard of whey being given in Dublin, but could give no particulars of cases. I determined to try it. Beginning very gently and watching the patients' hearts very carefully I found that the heart's action improved on what to my mind appeared practical starvation. The result has been to reduce the death-rate of the cases under my care which had been 15.5 per cent. for the previous seven years to 2.7 per cent. for 73 cases. With the exception of two cases, all those cases which I bring forward have been treated by me at the Beacon Hill Isolation Hospital of the Faversham Rural District, and I take this opportunity of acknowledging my indebtedness to the matron and nurses who have had charge of the cases, when they were not themselves patients, for their carefulness and the interest which they have taken in the method of treatment.

The following table shows the comparative analysis of whey and cow's milk:—

*The Results of a Comparative Analysis of the Whey and Cow's Milk used, expressed in Percentages.*

	Whey.	Milk.
Total solids ... ..	7.4	12.43
Lactose ... ..	4.9	4.9
Fat ... ..	1.2	3.4
Albuminoids ... ..	0.8	3.3
Mineral matters ... ..	0.49	0.73

From this it will be seen that whey contains about half as much solids as milk does. The loss in fat is 2.2 per cent. and in albumin 2.5 per cent. Whey, therefore, practically consists of a solution of milk sugar with a small amount of fat, albumin, and salts. Science tells us that a male adult at rest requires daily three ounces of nitrogenous food, one and a half ounces of fat, 12 ounces of carbohydrates, an ounce of salts, and from 50 to 80 ounces of water. Taking four pints of whey as the average daily diet for adults the total in solids is roughly: three-fifths of an ounce of nitrogenous food representing a deficiency of  $2\frac{1}{2}$  ounces;  $1\frac{1}{2}$  ounces of fat representing a deficiency of three-tenths of an ounce; four ounces of carbohydrate representing a deficiency of eight ounces; and two-fifths of an ounce of salts representing a deficiency of three-fifths of an ounce. It is therefore a surprise to find from practical experience that the body can carry on its functions well for three months (Case 44) during an illness with high fever on a diet in which the nitrogenous food has been reduced to little more than half an ounce daily. Sugar of milk,  $C_{12}H_{22}O_{11}$ , contains no nitrogen; whisky, which is alcohol,  $C_2H_5O$ , with a little colouring matter, traces of essential oils, and water, also contains no nitrogen.

**Preparation of the whey.**—To each quart of new milk stir in two teaspoonfuls of rennet. Put it into a pan and warm slowly till it curdles. This takes about 20 minutes. Break up the curd and strain the whole through fine muslin. The curd is thus separated from the whey. A quart of milk yields about six ounces of curd. The rennet we use at Beacon Hill Hospital is freshly prepared by a local druggist and is thus free from salt. The whey prepared from fresh rennet is thus more palatable, but all of the ordinary rennets sold by druggists and grocers answer very well. As rennets are slightly variable in strength the correct amount to be used in each case to form a curd of sufficient firmness must be learnt by experience. More cream can be added to the whey if required. The whey can be sterilised in summer and made more palatable to some people by the addition of tea, coffee, or other flavouring material. For children, if it be coloured pink with a little cochineal, it makes them very happy. The quantity given varies from a pint and a half to six pints daily. In no case have I limited the quantity. If the whey be sterilised some lemon-juice should be given occasionally to prevent scorbutic symptoms. In only two or three cases did vomiting take place and in each instance it was shortly after admission and was probably due to undigested solids in the stomach. Two of these children passed fresh black currants and seeds. Most patients take whey well without any flavouring and they generally infinitely prefer it to milk. All the patients discharged have been sent out well, and I have not heard of any ill after-effects in any case. It is a difficult thing to reconcile these practical results with physiological data, and the physiological deficiency is the lack of nitrogen. True, many patients have had some beef-tea, but it was given as a variation in diet to make them feel happier or because there was constipation. It will be noticed in the table, however, that most patients had no beef-tea at all.

Some theorists maintain that the patient obtains his nitrogen from his own tissues. It matters not where he obtains it or whether he obtains it at all provided the practical result is good. Perhaps the system in enteric fever has the power of absorbing it from the atmosphere; perhaps it can do without it.

The amount of emaciation on this diet varies very much, but not more than it does on any of the usual diets for enteric fever. Some patients seem scarcely to lose weight, but the patient in Case 48 was so thin that the abdomen

appeared absolutely empty and the outline of the spinal column showed through the skin of the abdominal wall. She was troubled with the characteristic green motions sometimes found in enteric fever, but when the fever had gone she regained weight even faster than she had lost it.

The most marked beneficial effects of the whey diet are in the clean mouth and tongue. Even in the third week of the disease the tongue and mouth scarcely vary from the normal healthy condition. One never sees sordes, thick dry fur, cracked tongue, ulceration, *et hoc genus omne*, so that the patients' sufferings are at once halved and they have really little to complain of.

That the result of whey diet on the heart is good can be seen at once by the gradual diminution of the pulse-rate in nearly every case. In Case 44 the pulse was 60 after 11 weeks' use of whey diet, and in Case 33 it was 46 on the twenty-sixth day after admission.

The fatal cases of enteric fever were two and in one of these the disease was doubtful. Another case (21), a woman who was admitted suffering from uremia and who rapidly became comatose and died three days after admission from that condition, I have expunged altogether from my list as there was no evidence of enteric fever.

The first fatal case (Case 31) was a true death from enteric fever of a very severe type. On admission the patient had a weak dicrotic pulse. His temperature chart was an extraordinary one, there being scarcely any variation morning, noon, or night; he had profuse diarrhoea and perpetual hæmorrhages, and finally he collapsed with a profuse hæmorrhage following on very severe diarrhoea. I cannot but regret now that I did not use the cold-bath treatment in this case. The patient certainly would not have had so much exhaustion from the high temperature and it might have enabled him to withstand the effects of the deep ulceration that was evidently present. He was admitted at about the tenth day of the disease and kept a good pulse in spite of small hæmorrhage till the twenty-eighth day. On the thirty-first day his bowels acted seven times with hæmorrhage, on the thirty-second day 15 times, and on the thirty-third day 14 times. I believe the blood in the intestine was the cause of the purging and the purging aggravated the hæmorrhage, thus causing a "vicious circle." The actual cause of death may be classed as "hæmorrhage." I cannot believe that any different diet would have saved the patient. The patient in the other fatal case (Case 35) was a young man who had been in Cuba and had had "Cuban fever." He was yellow and cachectic on admission and was suffering from diarrhoea with very green stools containing much mucus. The pulse on admission was 116. His temperature kept hectic, as may be seen from the chart, and his symptoms were more those of dysentery and abscess of the liver. It was most difficult to get him to take his nourishment. After four weeks the temperature became normal and the loose motions ceased. He was well enough to sit up and I put him on semi-solid diet, but violent diarrhoea started immediately again and he died more than eight weeks after admission. It is very doubtful whether this was a case of enteric fever at all, but as there is doubt I thought it better to include it.

For many years there have been medical men in different parts of the world who have tried methods of dieting different from the routine milk diet. As far back as the "seventies" Mr. William Thomson of Melbourne in Australia, a man of much originality, an interesting writer, and a man with much experience of enteric fever, eliminated milk from the diet of his patients and fed them entirely on raw meat-juice and whisky. He was reputed to have lost only two cases in all his practice. Dr. O. F. Paget of West Australia records that he has treated well over 100 cases of typhoid fever without a death. He gives his patients large doses of olive oil by the mouth and the rectum, but he does not mention how he diets them. Recently Dr. F. J. Smith of the London Hospital advocated stopping all food for 24 hours if undigested milk or other food were found in the motions, varying the quantity of food according to the patient's appetite, and even giving nothing but cold water for four or five days at a time with the happiest results; but "milk is his sheet anchor," and he did not in his article mention his death-rate.

Since making up my table I have had one more case. The patient refused whey at first and spat out his nourishment, so I allowed him to go without nourishment altogether for

TABLE GIVING DETAILS OF 75 CASES OF ENTERIC FEVER IN WHICH THE PATIENTS WERE FED ON WHEY.

No. of case.	Age.	Sex.	Highest temperature in degrees F.	Duration of temperature after admission in days.	Highest pulse-rate.	Highest daily action of bowels.	Alcohol in ounces.	Whey.		Remarks.	Complications.
								Quantity in pints.	Duration in days.		
1	5	F	104.2	11	144	10	1½	2½	24	There was much tympanites. Turpentine enema, 10 minims in four ounces of water; oil enema for constipation. Otitis interna. The patient was sick at first till whey coloured with cochineal was given.	Spots; otitis.
2	4	F.	104.4	5	136	6	1	2	20	—	Slight hæmorrhage before admission.
3	52	M.	—	—	—	—	2	3*	22	—	Heart disease.
4	47	M.	—	—	—	—	2	3*	—	—	Pneumonia.
5	53	M.	—	—	—	—	2	3*	—	—	—
6	15	F.	—	—	—	—	{ 8 } 12	4	44	The patient passed urine unconsciously. A bad case; two relapses; got out of bed; picked a hole in her head. Also had meat essence (Brand).	Toothache.
7	20	F.	—	—	—	—	6	3	27	From Maidstone epidemic. Also had 10 ounces of beef-jelly daily.	—
8	2	M.	—	—	—	—	1	3	13	Two minims of tincture of opium four times a day for five days.	Peritonitis.
9	7	F.	—	—	—	—	0	2½	20	Also had beef-tea and the white of two eggs. Periostitis of the tibia afterwards.	Diarrhœa; otitis; endocarditis.
10	13	F.	—	—	—	—	3	{ 3½ } 4	40	Very slight hæmorrhage; cough; leucorrhœa; relapse.	Heart; otitis.
11	16	M.	—	—	—	—	4	4	5	—	Pericarditis.
12	17	F.	—	—	—	—	—	4	39	Had beef-tea also after 21 days. Note 10 days after admission: "Has had nothing but whey. Pulse 72, good. Cardiac first sound excellent."	—
13	26	M.	—	—	—	—	—	3*	21	—	—
14	25	F.	—	—	—	—	{ 2 } 4	4	14½	—	Albuminuria; hæmorrhage; phlegmasia alba dolens.
15	25	F.	—	—	—	—	½	3	14	Did not abort.	Pregnancy, three months.
16	5	M.	—	—	—	—	—	3	18	—	—
17	6	M.	—	—	—	—	—	3	{ 5 } 23	Relapse on the fifteenth day.	—
18	36	F.	103.2	17	114	C.	—	4½	21	Slight attack. (C. here and elsewhere signifies constipation.)	—
19	5	M.	104.2	{ 28 } 18	{ 140 } 112	4	{ 3 } 2	3	{ 37 } 29	Also half a pint of beef-tea flavoured with vegetables. A long severe case with relapse.	Acute meningitis.
20	11	M.	101.4	14	116	4	—	3½	20	—	—
22	48	F.	102.4	21	104	6	6	3	30	The patient had eaten oysters 14 days before admission. Abdomen very doughy. Opium for diarrhœa.	Aphasia (temporary).
23	61	M.	103.0	26	88	3	3	4½	43	Olive oil enemata for constipation. Later slight rise of temperature from tympanites.	—
24	27	F.	103.0	17	110	6	2	3½	24	The whey was slightly flavoured with tea. Fifteen minims of tincture of opium for diarrhœa.	Pregnancy; aborted thirtieth day.
25	9	M.	104.2	21	112	2	—	3½	30	Sponged occasionally.	—
26	4	F.	102.8	9	120	2	—	3	20	—	—
27	28	F.	99.2	20	62	C.	—	3½	30	The temperature did not go to 100° F. throughout.	—
28	12	F.	103.0	21	112	2	—	3½	34	—	—
29	13	M.	104.2	5	106	C.	3	3½	14	—	Epileptic.
30	7	M.	104.2	16	126	4	2	3½	51	An interesting drop in the temperature from 102° to 97° F. occurred without apparent cause. Afterwards a constipation temperature.	—
31	21	M.	104.4	25	122	15	4	4	25	The temperature varied from 103° to 104° F. for the first week. Was admitted with dicrotic pulse. Three hæmorrhages. Most severe and profuse diarrhœa. The patient died rather suddenly.	—
32	12	M.	103.4	4	100	C.	—	3½	17	Apparently an abortive attack as in Case 29 (a brother of this patient).	—
33	24	M.	104.2	24	94	{ 3 } C.	2**	4	25	The pulse 52, good, after 25 days on whey only. Enormous appetite when convalescent.	—
34	24	F.	103.4	17	118	2	—	4½	25	The pulse came down steadily on whey.	—
35	22	M.	103.0	30	136	6	2	4	42	A cachectic anæmic man who had fever in Cuba. Much slimy diarrhœa. ? Dysenteric. Very difficult to feed. After the whey was left off the diarrhœa was lienteric. The patient was very depressed. Vide chart.	Cuban fever; cachexia.
36	9	F.	104.0	24	144	4	3	3	35	A good whey case. Perpetual diarrhœa for over three weeks, with fever, but the pulse steadily improved.	—
37	13	F.	103.4	21	128	2	3	3	32	Spots.	—
38	7	F.	102.6	13	132	3	3	3	28	—	—
39	14	F.	102.8	14	126	4	—	3	25	A sister of the last two patients. She took no alcohol, so her case compares well with Case 38.	—
40	8	M.	104.6	29	144	5	{ 2 } 4	{ 3 } 4½	42	A severe and long attack. There was much abdominal distension which was relieved by turpentine enemata.	Cerebral irritation with cough.

TABLE GIVING DETAILS OF 75 CASES OF ENTERIC FEVER IN WHICH THE PATIENTS WERE FED ON WHEY—(Continued).

No. of case.	Age.	Sex.	Highest temperature in degrees F.	Duration of temperature after admission in days.	Highest pulse-rate.	Highest daily action of bowels.	Alcohol in ounces.	Whey.		Remarks.	Complications.
								Quantity in pints.	Duration in days.		
41	38	M.	103.6	29	112	7	{ 3 } 8	4	29	A recrudescence of temperature on the twelfth day after normal lasted 13 days due to abscess over the sacrum. A long and severe case.	Hæmorrhage.
42	2	F.	101.0	7	106	2	0	3	21	A daughter of the patient in Case 41.	—
43	22	M.	104.4	31	130	13	4	4½	42	—	Toothache; delirium.
44	21	F.	105.0	{ 38 } 8 14	120	6	3	4	89	On the thirty-ninth day of the disease the pulse was 96, full and good, on whey and whisky only. The patient lived on whey and whisky for 89 days. No diarrhoea.	Gland in neck afterwards; phlebitis.
45	32	F.	103.2	11	136	1	4	4	28	—	Constipation.
46	24	M.	100.8	9	98	7	0	4	19	—	—
47	6	M.	103.6	{ 46 } 8	140	6	½	{ 3 } 4	61	Long-continued fever with high pulse, followed by constipation temperature.	Diarrhoea for three weeks.
48	32	F.	105.0	45	128	8	{ ½ } 1	4	58	The mother of the last patient. Hæmorrhage of clots for 10 days. Grass-green motions relieved by salol. Very thin. Interesting case.	Hæmorrhage; hysteria; green motions; diarrhoea.
49	28	M.	104.0	21	104	6	{ 4 } 6	5	28	A brother of the patient in Case 46. Suppression of urine for 24 hours; dicrotic pulse; hæmorrhage. Arteritis in the leg afterwards, with slight slough on the toe.	—
50	5	M.	—	—	—	—	—	4	21	No rise of temperature after admission.	—
51	23	M.	105.0	35	120	17	3	{ 4 } 5	{ 48 } 5	The patient had eaten mussels from the sewer opening at Whitstable. There was much diarrhoea; coma vigil; muscular tremors. Steady improvement of the pulse.	—
52	13	M.	103.8	18	108	4	0	4½	49	Bowels not being opened for eight days caused a rise of temperature for eight days.	—
53	20	M.	103.8	18	94	3	0	4½	43	Peeling with scarlet fever and ill with typhoid fever when admitted.	—
54	33	M.	103.8	20	100	1	0	3	31	Retention of urine on admission. Temperature normal in four days; three weeks later the temperature was for 21 days typical of typhoid fever.	—
55	9	M.	104.0	7	126	8	0	3	20	One of six patients in the same family.	—
56	20	M.	103.8	7	84	1	0	4	22	Spots.	—
57	28	F.	104.0	21	120	4	0	4½	35	Had a miscarriage. She did washing for a typhoid fever case at Kennaways Hospital.	—
58	11	F.	103.0	11	116	7	1	2 or less ¶¶	25	Spots. Troubled with vomiting on admission. Retained nothing but brandy-and-water for three days.	—
59	13	F.	104.6	23	124	6	6	3½	30	Passed motions unconsciously. Typhoid voice, high-pitched and querulous.	—
60	6	F.	105.2	24	126	7	2	2½	30	Green motions. Sponged. Took little whey. Salol, three grains three times a day.	—
61	29	M.	100.0	1	72	1	—	4	15	Ill three weeks before admission. Spots; hæmorrhage.	—
62	43	M.	103.8	37	100	4	1	{ 4 } 6	22	The sixth case from one house. Spots; much blood in the urine.	Acute nephritis.
63	32	M.	104.0	20	118	1	3	5	38	Acute purulent bronchitis. ? Typhoid. Was re-admitted after previously being discharged.	—
64	32	M.	103.0	5	92	1	0	4	17	Ill about a fortnight. Spots. Re-admitted above.*	—
65	7	F.	99.6	7	66	2	0	3	8	Probably not typhoid fever.	—
66	7	F.	104.8	21	132	3	0	3½	41	Same as last case. ? Caught typhoid fever in the hospital.	—
67	4	M.	105.6	10	134	11	1	2½	36	Green motions. Three grains of salol. Passed a whole black currant in motions, also seeds.	Scurvy.
68	—	—	103.0	—	—	—	—	—	—	A private case. The patient was nursed by his wife.	—
69	—	—	—	—	—	—	—	—	—	A private case.	—
70	27	M.	103.2	23	112	5	3	4	34	Only passed two ounces of urine in the first 18 hours. No albumin. Had eaten oysters.	—
71	17	M.	103.0	6	84	2	3	4	22	An abortive case of undoubted typhoid fever.	—
72	—	—	—	—	—	—	—	—	—	An ordinary case.	—
73	—	—	—	—	—	—	—	—	—	A severe ordinary case with steady pulse.	—
74	—	—	—	—	—	—	—	—	—	A peculiarly slow, steady pulse.	Relapse.
75	—	—	—	—	—	—	—	—	—	A doubtful case. ? Only pneumonia or abortive typhoid fever. Constant diarrhoea.	—
76	20	M.	104.0	—	90	5	4	4	32	An enormous hæmorrhage, almost three pints on the twenty-sixth day, also on the twenty-seventh and twenty-eighth days; dicrotic pulse 84 afterwards.	—

Counting Cases 63, 64, 65, and 66 as two cases and omitting 21 = 73 cases.

\* And one pint of milk. † Then milk and whey. ‡ And beef-tea. § Beef-tea after 20 days. ¶ Beef-tea after 14 days. ¶¶ Epidemic.  
 \*\* After 15 days. †† Beef-tea after the twenty-fifth day. ‡‡ Chicken broth after the twentieth day. §§ Beef-tea on the thirtieth day  
 ¶ Cream and beef-tea. ¶¶ Soda-water. \*\*\* Jelly. ††† Beef-tea and jelly.

24 hours. He then took the whey and liked it exceedingly well and has made a good recovery.

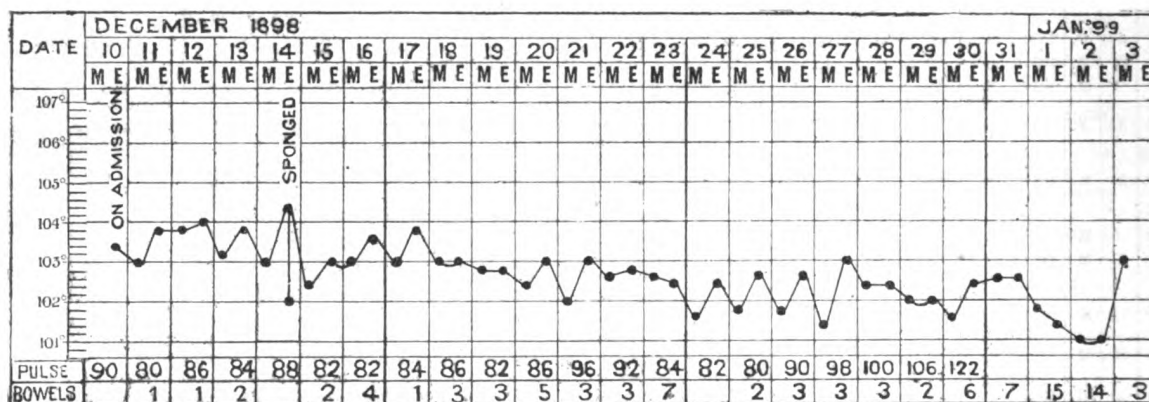

In Cork-street Fever Hospital, Dublin, the death-rate for about 15 years is about 7.5 per cent. Dr. J. M. Day, the resident medical officer, writes to me that his treatment is sweet whey, white of egg, and broth chiefly. He does not use milk if there be tympanites, diarrhoea, hæmorrhage, or any evidence of its disagreeing with his patients, and never gives children milk except in very mild cases. It is probable, therefore, that it was to Cork-street Fever Hospital that my Canterbury friend referred.

Besides those who have written on the subject one hears of a growing tendency amongst medical men to feed enteric fever patients on white of egg, barley-water, and veal broth. The death-rate of the Maidstone epidemic was only about 8 per cent. This much we know, but we would also much

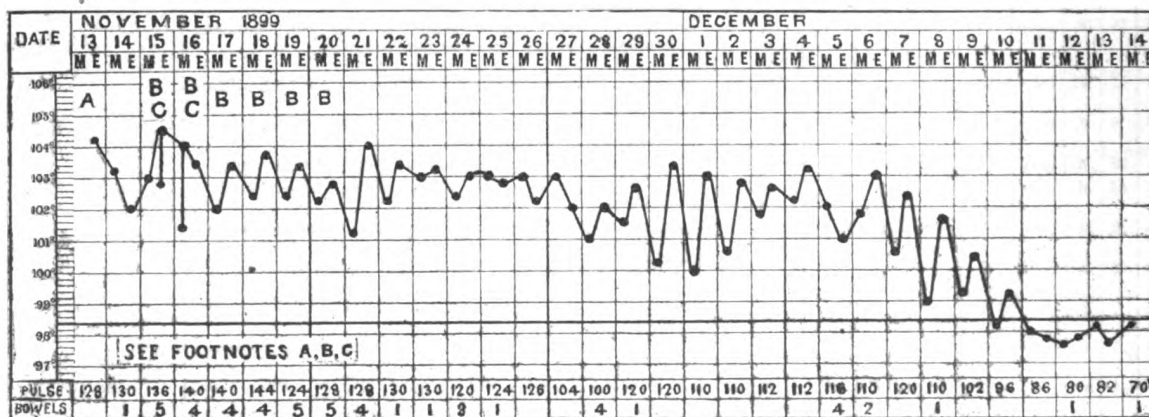

where a patient is hungry and is not given enough to satisfy his appetite. Moreover, he takes an intelligent interest in his own case. As I once knew a case of relapse on the fifteenth day, I keep the patient on the diet until 15 days after the temperature has regained its normal rate. This may be thought four or five days longer than is really necessary, but it absolutely does away with any risk of relapse from too early feeding. One frequently gets a slight rise of temperature during this fortnight if there be much constipation, but an enema of half a pint of olive oil generally removes it. In cases with such rises of temperature it is always well to examine the teeth, for I have on many occasions—and this is particularly the case after scarlet fever—found that an aching tooth which the patient had not mentioned has caused the rise of temperature.

It is wonderful how little trouble patients treated in this

like to know how those cases were treated—whether they were all treated on milk or whether they were treated without milk. It would be a great kindness if the medical men of Maidstone would enlighten us. In epidemics one expects a lower death-rate than in sporadic cases, because the early recognition of the disease halves the danger and certainly modifies the severity of the attack.

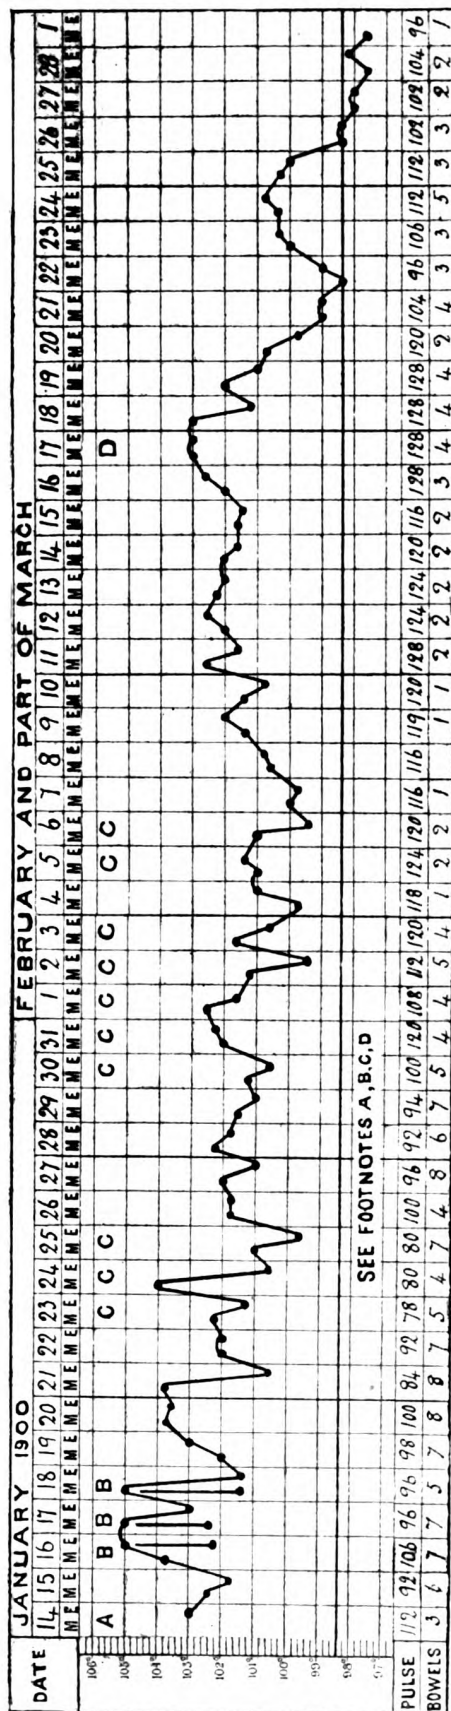

In treating cases of enteric fever I always find it a great assistance, if the patient be old enough to understand, to explain to him that the disease is an ulceration of the bowel and that he must be kept on the diet to prevent the risk of food scratching a hole in the bowel. He is flattered at being taken into one's confidence and fully and easily appreciates the necessity for it from a common-sense point of view. After doing this it is seldom that one hears the usual complaints that are inseparable from a condition

way are to the practitioner and the nurse. Even when they are admitted in a state of delirium it very rapidly disappears and the mind becomes clear and the patient quiet and easy to manage. Instead of keeping the medical man in a state of perpetual anxiety and worry, necessitating, perhaps, three visits in the day, they do so well that they can be seen at his convenience and when they are seen require seldom more than the usual examination of tongue, pulse, heart, palpation of the abdomen, inquiry as to quantity of urine and freedom from albumin, and the directions to the nurse to "go on the same." One case, that of a young man in a cottage with a sensible little woman for a wife, was treated at home and did as well as those in hospital. In such cases I would urge the absolute necessity of explaining the disease and the treatment, and the nurse will not then feed her patients on apples and grapes.

CLINICAL CHART OF CASE 35.

CLINICAL CHART OF CASE 48.

Alcohol is a most important factor in feeding in enteric fever cases. Sixteen of my patients had no alcohol, but the majority of them had from one to four ounces daily. In Case 6 the patient, a female, aged 15 years, had as much as 12 ounces and in Case 59 the patient, aged 13 years, was given six ounces. Both of these patients had the querulous, high-pitched voice so characteristic of enteric fever and were weak in intellect for a short time after convalescence. In both of these cases the alcohol was pushed because the cardiac first sound was weak—and in such cases the alcohol *must* be pushed to any extent. I have given 24 ounces daily before beginning this treatment. From two to four ounces for adults seem beneficial and never do any harm, acting as a food and lessening tissue change, and I would always advise that a small quantity be given. I use whisky or brandy, as the patient prefers.

A symptom one meets with perhaps once in 20 cases is grass-green motions. I have found from five to 10 grains of salol three times a day rapidly cure this, and since beginning the use of salol I have never had to use any other drug for it.

*Fever.*—In no case have I had to resort to the cold bath, though I now think that the patient in Case 31 would have been the better for it. In the first place, I never allow the patient more than one sheet over him as bed-clothes, even if he complains of feeling cold. If his temperature goes higher than 103° or 104° F. I have him sponged and placed under a cradle with one or two icebags suspended inside and a sheet over the top. This forms a cold-air bath and is quite efficient.

*Hæmorrhage* occurred in five or six cases, including Case 31, a fatal one. The other cases gave no trouble, though the patient in the last case in my list had an enormous hæmorrhage measuring over two pints. In this case a pulse of 84 was kept after the hæmorrhage and the patient made a good recovery. We may assume that no treatment will prevent the possibility of an occasional hæmorrhage so long as ulceration occurs, for it is the natural sequence of ulceration, but one hopes that in the future a means of preventing the ulceration will be discovered. It is quite possible that large doses of salad oil would saturate the sloughing Peyer's patches, and by stopping the supply of nitrogen to the bacilli so prevent further ulceration.

One may generalise and say that drugs are required only for complications. In the space at my disposal it is quite impossible for me to give an account of all the cases, for each one in itself is a clinical lecture, but some of the more interesting charts are reproduced and I have tabulated all the cases, giving the age, the sex, the highest temperature, the duration of temperature after admission, the highest pulse, the highest daily action of the bowels, the amount of alcohol given, the quantity of whey administered daily, and the length of time that the patient was kept on whey, as well as remarks on anything that made the case especially interesting, and as to complications. The general severity of each case will be gathered from these data, and I think that we may regard them as a very fairly average lot of cases, such as might come under treatment in any hospital, and thus fairly to be taken to compare the results obtained with those obtained elsewhere. Unfortunately in 21 cases the temperature charts were destroyed, so that the table is incomplete, but there are still sufficient to be of interest.

Every case of enteric fever is of intense interest, for the variety is so enormous. In the paper which I read at Canterbury, already alluded to, I enumerated 22 complications which I had met with, and I am sure that those who discussed the paper afterwards added quite as many more.

In spite of my strong advocacy for this line of treatment I do not desire to be dogmatic, for every case must be treated on its merits according to the judgment of the practitioner who is attending it, but I do, and shall always, insist that milk diet is the wrong diet and I have done my small best to prove that it is so. Theoretically I believe that enteric fever patients would do as well on an artificial whey and salad oil as on anything else, but I trust that this will be investigated in the future. So long as my patients continue to do as well as they do at present I shall be satisfied with my present treatment, but should occasion arise to make me dissatisfied I shall seek to improve the diet and shall then publish the result.

As a last word I would urge practitioners to give the treatment a fair trial and to let their results be known. I cannot but believe that the present high death-rate is unnecessary, and if this is the case it calls for radical

alteration, and we should not rest satisfied till for the whole of England our death-rate from enteric fever is a cypher. Teynham, Kent.

## ADVANCES IN THE TREATMENT OF DISEASES OF THE NOSE.

By H. LAMBERT LACK, M.D. LOND., F.R.C.S. ENG.,  
SURGEON TO THE HOSPITAL FOR DISEASES OF THE THROAT,  
GOLDEN-SQUARE.

IN the treatment of diseases of the nose very great advances have been made within recent years. For example, the subject which, perhaps, more than any other occupies the attention of the modern rhinologist is not even mentioned in Morell Mackenzie's work on Diseases of the Nose—that of the diseases of the accessory sinuses and air-cells. True, acute suppuration in the antrum of Highmore is described by John Hunter, an affection usually of dental origin and associated with swelling, redness, and oedema of the cheek. But this affection is extremely rare, whereas suppuration with no external signs is comparatively common and yet has attracted attention only during the last 15 years. Ziem, who first described it, was himself a sufferer and for years sought the advice of his colleagues in vain for a foetid discharge from the nose. At length he himself divined the cause and had his antrum opened and was cured. Being now on the look-out he soon discovered that the disease was not infrequent, and more recently it has been found that suppuration in the frontal and other sinuses is almost as common as suppuration in the antrum. Thus a surgeon became famous and opened up a new field for surgical enterprise through the fortunate accident of having his own body to study on. Truly "it is an ill wind that blows nobody good." [The anatomy of the nose and its accessory cavities was briefly described and illustrated with lantern slides and specimens.]

### SUPPURATION IN THE NASAL SINUSES.

Antral suppuration is often due to caries of the teeth, but that this is not the only cause, as has often been said, is shown by the fact that the teeth cannot possibly cause suppuration in the frontal or other sinuses. The most common causes are severe nasal catarrhs, especially when associated with infectious fevers, influenza, &c. The recent epidemic of influenza, in addition to its other sins, is probably responsible for the large number of cases of this kind seen at present, as well as for the large and increasing prevalence of nasal polypi.

An acute catarrh of a sinus is commonly associated with a nasal catarrh and if then the outlet of the sinus becomes blocked acute suppuration will result. The openings of the sinuses are small and ill-situated for drainage and a moderate amount of catarrhal swelling alone is sufficient to occlude them. The majority of these acute suppurations get well spontaneously, but in some cases chronic suppuration results. This may be due to several causes. The intensity of the original inflammation may irretrievably damage the mucous membrane lining the sinus; there may be an obstruction to the outlet of the sinus from thickening of the mucous membrane or bone or from polypi preventing a free escape of the discharge; and ultimately the persistence of the suppuration may induce changes in the lining membrane or bony walls of the sinus. Again, a chronic disease in the nose may maintain a chronic catarrh in a sinus, or the cavity may contain a foreign body—thus a tooth may be found in the antrum. The usual history of an acute case is that the patient experiences a sudden increase of the nasal symptoms with a feeling of heat, fulness, and distension in the nose and over the region of the affected cavity. There are pain and tenderness and in many cases severe neuralgia shooting along the trigeminal nerve. In a few of the more severe cases there may be much constitutional disturbance, and the soft tissues overlying the cavity may become swollen, red, and oedematous. The feeling of tension is much increased on straining, coughing, or lowering the head. After a few hours or days of increasing suffering there is a sudden discharge from the nostril on the affected side, consisting of muco-pus or pus, mixed with more or less blood, and the symptoms are at once relieved. This may be the end of the attack, or after a brief interval

the symptoms may return and increase in severity until a second discharge takes place. This cycle of events may even be repeated, but in the end complete recovery usually ensues. It is important that these cases should be recognised and appropriately treated, because if the suppuration should continue secondary changes will occur in the lining membrane and walls of the sinus which will lead to chronic suppuration and make the cure a matter of great difficulty. On the other hand, in early cases cure is usually an easy matter.

The chief object of treatment is to reduce the swelling around the opening of the cavity and to allow free escape into the nose for the pent-up discharge. The nose should be washed out by means of an alkaline lotion such as Dobell's. The formula for this is three grains each of bicarbonate of soda and borax and one and a half grains of carbolic acid with a little glycerine or sugar to an ounce of water. It is the most useful of all nasal lotions and is capable of much variation. Thus the carbolic acid may be omitted when it seems irritating, salt or chloride of ammonium may be added when a stimulant is required, and hazeline may be introduced when an astringent is required, and so on. This lotion should be used until all catarrh has ceased. Of the special measures to reduce the swelling around the opening of the cavity the best is the application of a solution of suprarenal extract and cocaine. Suprarenal extract is a recent introduction of great value in all nasal work. It increases the anæsthetic action of cocaine and prevents its absorption. It is a strong astringent to the nasal mucous membrane, rendering it white and bloodless, so that operations may be performed on the nose without the loss of a drop of blood. To obtain the full effect the solution should be freshly prepared. Ten grains of extract of the dried gland should be dissolved in 100 minims of distilled water, filtered, and 10 grains of cocaine added. Pledgets of wool soaked in this solution should be packed into the nose high up under the middle turbinate, and retained there for from 20 to 30 minutes to obtain the full action. If the frontal sinus be affected discharge soon commences to trickle down into the nose; should the antrum be at fault, the evacuation of the cavity may be facilitated by lowering the patient's head and bending it over towards the opposite side. Subsequently any hypertrophy or swelling should be removed, the depletion caused by the local blood-letting tending to prevent recurrence of the swelling. In fact, should this treatment not be effectual, incisions simply to produce local blood-letting should be tried. Subsequently, to keep the passages clear the best application is a spray of menthol, from 5 to 10 per cent., dissolved in almond oil or paroline, and hot fomentations should be applied, as they relieve the pain and are very grateful to the patient. If these measures fail active means must be adopted to secure the evacuation of the cavity. If the maxillary antrum be affected it should be punctured and the pus should be washed out by irrigation. The particular method to be adopted depends on various circumstances. If the adjacent teeth are carious they should be extracted and the antrum should be perforated from a socket with a small drill. This little operation is easily done under gas. The first molar is the site of election, as its roots are separated by a very thin plate of bone from the floor of the antrum; but should the first molar be healthy it is quite easy to reach the sinus through the socket of the second molar or either of the bicuspid teeth. Having made an opening the nozzle of an antrum syringe is inserted and the cavity is washed out with a solution of boracic acid, boiled salt solution, or other unirritating fluid. This irrigation must be repeated daily until the discharge ceases, but, as a rule, in these acute cases no pus will be seen after the first washing and after two or three days the treatment may be discontinued and the opening allowed to close. On the other hand, when no carious teeth are present and when there is no vacant space in the alveolar border the antrum should be punctured from the inferior meatus of the nose. A pledget of wool soaked in cocaine is packed in beneath the inferior turbinate and then a small trocar and cannula are passed into the nose and directed strongly outwards about half an inch behind the anterior extremity of the inferior turbinate so as to bring it into contact with the antro-meatal septum at its thinnest part. It is then pushed onward into the cavity, the trocar is withdrawn, and the cavity is washed out through the cannula. This operation has the advantage that it does not entail the sacrifice of a healthy tooth when no carious tooth or vacant space is

present, that it only requires cocaine anæsthesia, and that it does not establish a communication between the nose and the mouth. On the other hand, this opening cannot be maintained and therefore the operation has to be repeated daily or as often as necessary until a cure is established.

I have gone somewhat fully into the diagnosis and treatment of these cases as they are commonly met with in general practice and their treatment is easily conducted and very satisfactory.

*Chronic suppuration* is a much more difficult matter to treat. In the first place the single symptom is a purulent discharge from the nose and the diagnosis is difficult and in many cases impossible. One important rule may be laid down, that in every case in which there is a purulent discharge from the nose there is most probably suppuration in one of the sinuses, and further that although suppuration in the antrum, or indeed in any sinus, may be met with alone, in the majority of cases two or more sinuses are simultaneously involved. When no external sign of disease is met with the first point in determining the origin of the pus is to ascertain the position at which it appears in the nose. Thus pus coming from the middle meatus implies suppuration in the antrum, frontal sinus, or anterior ethmoidal cells. Pus appearing in the posterior part of the nose and coming from above the middle turbinate means suppuration in the posterior ethmoidal cells or sphenoidal sinus. Another method of diagnosis, reliable only in disease of the antrum, is transillumination. The patient is examined in a dark room; a small but powerful electric light is placed in the mouth and if the antra are normally clear the cheek will be lighted up, a bright band will appear along the infra-orbital margin, the pupils will be lighted up, and the patient will experience a subjective sensation of light. When the antrum contains pus the bright band along the infra-orbital margin is absent, the pupil is dark, and the patient sees no light. These signs are obviously much more definite when one antrum only is affected. But the one really reliable means of diagnosis is exploration by means of puncture and irrigation. In the majority of cases it is possible to differentiate disease of the anterior set of sinuses, namely, the antrum, the anterior ethmoidal cells, and the frontal sinus, from disease of the posterior set, the sphenoidal sinus and the posterior ethmoidal cells. If there is no definite evidence as to which of the anterior set of sinuses is involved, the antrum should be first attacked, then the ethmoidal cells, and lastly the frontal sinus. If the posterior set of cavities be affected the posterior end of the middle turbinate should be removed, and then either the posterior ethmoidal cells opened, or, the ostium of the sphenoidal sinus having been brought into view, this cavity should be washed out through its natural opening. An important rule to bear in mind is that in every case it is necessary to explore the cavities one by one until all sources of suppuration have been discovered, for commonly more than one cavity is affected.

The treatment of chronic suppuration consists, in the first place, in adopting simple measures. Any abnormality or disease of the nose should be removed and the approach to the outlet of the affected cavity thoroughly cleared. The antrum should be washed out through a simple puncture as already described. The sphenoidal sinus can be irrigated through its natural opening and attempts may also be made to pass a cannula up through the infundibulum into the frontal sinus. Should these means fail after prolonged trial the question of further operation must be discussed. In some cases the patient is better left alone; in others a radical operation must be undertaken. The affected cavity must be freely opened, all pathological conditions set up by the suppuration and tending to maintain it, such as polypi, caries, or necrosis of the walls, must be removed and means must be taken to prevent reaccumulation of the pus either by providing permanent free drainage or entirely obliterating the cavity. In the antrum a free opening is made through the canine fossa, any pathological products are removed, and then, by cutting away the wall separating the antrum from the inferior meatus of the nose, free permanent drainage is established. The canine fossa opening is allowed to close. The frontal sinus is opened through the supra-orbital margin, its anterior and inferior walls are chipped away, the lining membrane is entirely removed and the infundibulum is enlarged to admit of the passage of a large drainage-tube, and thus the sinus is entirely obliterated. The ethmoidal cells are best attacked from the nose with a sharp ring knife. The middle turbinate is first removed and then the ethmoidal cells

are thoroughly broken down and scraped away. The sphenoidal sinus is treated by enlarging its natural opening with punch forceps, such as Grünwald's, and the greater part of the anterior wall of the sinus may be clipped away. These measures are attended with a very fair degree of success, especially when it is possible to obtain complete obliteration of the sinus. They are not invariably successful, but our knowledge and means of dealing with these cases is constantly increasing, and before long better results may be expected.

Another great recent advance has been made in the treatment of *nasal polypi*. The methods of dealing with severe cases of this affection have hitherto been most unsatisfactory. Recently polypi have been ascribed to supuration in the accessory sinuses; they are, indeed, very commonly associated with it, but they may occur independently. The real cause of the frequent recurrence of polypi is disease in the underlying bone. This theory can perhaps hardly be described as new, for Morell Mackenzie relates two cases in which recurrence of nasal polypus was prevented by removing some of the underlying bone, and the view had been urged as long as 100 years previously. Dr. Woakes 15 years ago strongly advanced similar opinions. These observations, however, had been neglected, but during the last year my own investigations have again aroused the controversy and have been confirmed by others. They show that in all cases of constantly recurring polypi a peculiar form of a rarefying osteitis is present, and it is upon this that the obstinate nature of the affection depends.

The treatment therefore resolves itself into removing, not only the polypi, but also the underlying diseased bone. In simple cases the wire loop of the snare may be made to include a piece of bone as well as the polypus. In more severe cases, after the polypi have been removed, the parts may be cleansed and anæsthetised with cocaine and the bone may be cut away with punch forceps. In the worst cases more radical means should be adopted. The patient should be placed under a general anæsthetic, the polypus should be removed with polypus forceps, and then the whole ethmoidal region should be thoroughly curetted with a sharp ring knife. It is impossible to see what is being done, but if care be taken and the sharp edge of the knife be directed outwards rather than upwards there is little danger of wounding the cribriform plate, and should the inner wall of the orbit be injured no harm will result. The healthy ethmoid is firm and resistant and the knife gets little hold, but the carious softened bone is easily scraped away and the curetting should be continued until every soft piece of bone or degenerated mucous membrane has been removed. The hæmorrhage from this proceeding is free and necessitates considerable caution with the anæsthetic. It usually, however, soon ceases, but in some cases it is necessary to pack the nose. The subsequent treatment consists in irrigating the nose until healing occurs. By these means a complete cure may be obtained in the worst cases of nasal polypi in which frequent recurrence has occurred for many years under the ordinary treatment. It is not, however, an operation to be lightly undertaken. Both the operation and the anæsthetic require the greatest care and it should never be carried out in patients who are not in good health or who are more than 40 or 45 years of age.

*Trigeminal neuralgia*.—The more our knowledge of local diseases of the nose and mouth increases and the more carefully these parts are examined the more frequently this severe disease will be found to arise from a purely local cause. In fact, it is doubtful if all cases are not of purely local origin. A large number depend upon diseases of the teeth, such as Rigg's disease, or an unerupted tooth. Many others depend upon disease of the nose. Sinus supuration is a frequent cause and many a case of severe intractable neuralgia has been cured by simply opening the antrum. Another frequent cause is enlargement of the middle turbinate. This is liable to swell, and then it produces considerable pressure between the mucous membrane of the turbinate and the septum which may start a severe attack of neuralgia. Before prescribing medicinal remedies, therefore, local causes, especially in the nose and teeth, should always be sought for.

*Hay fever and paroxysmal rhinorrhœa*.—The symptoms of hay fever are well known, and an affection analogous to, but not identical with, hay fever is even more commonly met with. In these latter cases the symptoms—sneezing, nasal obstruction and profuse running at the eyes and nose—come

on regularly every morning, varying much in intensity, sometimes lasting an hour, sometimes five or six hours. The patient may have two bad attacks a day or may pass three or four days without an attack. Sometimes an exciting cause may be noted; in other cases none can be discovered. Inhaling dust, various smells such as those of roses and violets, the emanations from certain fabrics such as oriental carpets, draughts, the change from a warm room into a cold one, going out-of-doors, may in various cases set up an attack.

The treatment of these cases is identical with that of hay fever and, although it is impossible to be quite certain that a cure will be obtained in any given case, still, local treatment should always be adopted. In the first place any abnormality of the nose should be rectified, a polypus, a hypertrophied turbinate, a septal spur should be removed. Should this fail the best treatment is cauterisation of the nasal mucous membrane. By examining the interior of the nose with a probe very sensitive spots may often be discovered in some part of the nasal mucous membrane. These spots are often found in the region of the anterior end of the middle turbinate and on the opposite part of the septum. They should always be sought for, and if found should be destroyed by the electric cautery. Should this fail the inferior turbinate should be cauterised: this treatment is empirical, but by it the majority of cases may be cured and practically all of them at least temporarily relieved. These measures should be combined with the regular use of nasal alkaline lotions and in addition an oily spray, such as almond oil containing 5 per cent. of menthol, will be found extremely useful. A caution must be here added. Relief, or temporary relief, of the affection during the actual attack may always be obtained by the use of cocaine. The symptoms are relieved in two or three minutes, but the treatment has to be repeated every hour or so. Thus the remedy is a very dangerous one and especially so because in time the drug loses its effect, stronger solutions are required, and severe constitutional depression, insomnia, loss of appetite, and mental disturbances may result. In spite of this, the patient may resort to the drug because of the great relief it gives and thus may originate the cocaine habit. Further, the continued use of this drug apparently aggravates the local condition and renders it far more obstinate to curative measures.

*Asthma*.—There has been, and is, great dispute as to the pathology of asthma, and many nasal specialists consider asthma to be a purely reflex condition resulting from some pathological change in the nasal mucous membrane. I cannot assent to this proposition and would rather not express any opinion on the etiology of asthma in general. It is an undoubted fact, however, that by treating the nose alone a large number of cases of asthma may be improved and a few may be cured. The probability of a case of asthma being dependent upon nasal trouble is increased if any definite sensitive area or "cough spots" can be discovered in the nose or if, as is not very uncommon, the asthmatic attack is preceded or accompanied by the sudden onset of such symptoms as sneezing, nasal obstruction, and rhinorrhœa.

In the treatment of asthma, therefore, such conditions as nasal polypi, hypertrophied turbinates, and septal deflections should be rectified. In children adenoids should be removed. Sensitive spots in the nasal mucous membrane should be sought for and destroyed with the cautery. If no objective abnormality be found, but yet the onset of asthma be preceded by nasal symptoms, the inferior turbinates should be cauterised as in rhinorrhœa. On the other hand, if the nasal mucous membrane be healthy and there is no clear history of nasal disturbance preceding the asthmatic attack, nasal treatment should not be adopted. As I have said, the results are uncertain and there is no means of determining beforehand which cases will benefit by intranasal treatment. The most successful may be those in which there is no marked disease in the nose.

To turn to a more homely subject the large number of infallible remedies for a *common cold* are still being added to. The latest is cinnamon tabloids. It is directed that at the commencement of a cold two of these should be given every half-hour for three doses and then one every hour for the next 12 hours or until all symptoms have passed off. Apparently they do good in some cases, but I have tried them on myself without any benefit. Orthoform applied locally has also recently been recommended. This drug is a most valuable analgesic in cases of painful ulceration, especially

in the upper air-passages; it is non-poisonous and therefore may be used freely. Taken as a snuff it is said to relieve the excessive irritation of the nasal mucous membrane and thereby to stop the sneezing and excessive discharge. I have not yet had an opportunity of trying it. But in spite of all these drugs I expect that the only reliable remedy is opium or morphia in some form given in sufficient quantities to produce sleep in conjunction with the usual household remedies, which usually take the form of hot whisky-and-water or hot lemon-and-sugar as the case may be.

And now I would conclude with a caution against excessive operating on the nose. Great advantage has followed operations for nasal obstruction, and especially in children, but, as is natural, the zeal of many has outrun discretion and the number of diseases which are claimed to have been cured by the removal of adenoids is so great that the operation is in danger of becoming a panacea. This is partly due to the fact that patients nowadays rarely need encouragement to undergo operation; in fact, they are not happy till they get it, and if it is refused or postponed they go off elsewhere to have it done.

The advantage of normal nasal respiration in children is well recognised. Apart from the local relief to ear and throat troubles the effect on the general well-being is even more marked: stunted children commence to grow, the tendency to bronchitis and constantly catching cold disappears, and delicate children become strong and their intelligence even seems to increase. Should any such cause for the operation be found the removal of adenoids should certainly be undertaken. It is not likely to be followed by any ill result, although the occasional fatality which accompanies this operation should be sufficient to prevent indiscriminate operating. But in adults, in whom nasal obstruction often does very little harm, considerable care should be exercised before extensive operations are performed, and especially before the turbinates or other structures involving the loss of a large piece of healthy mucous membrane are removed. Certainly Nature is resourceful and is often equal to repairing the effects of surgical enterprise, but in many cases the dry nose and throat left after these operations puts the patient in a far worse plight than he was in before treatment.

Harley-street, W.

## THE REMOVAL OF SUPERFLUOUS HAIR BY A COMBINATION OF X-RAY EXPOSURE AND ELECTROLYSIS.

By DAVID WALSH, M.D. EDIN.,

HONORARY PHYSICIAN TO THE WESTERN SKIN HOSPITAL, LONDON, W.

THERE are few cosmetic operations more desirable from the feminine point of view than the removal of superfluous hairs from the face and other parts of the body. Short of operation various methods are in vogue, such as pulling out the hairs, shaving, and the use of depilatories. None of these plans, however, get at the root of the mischief, while they act more or less as local irritants that by stimulating the supply of blood to the part actually increase the growth of the hair. Depilatories destroy the shaft of the hair but they do not touch the hair bulb. They have been used from time immemorial, but their application would hardly be sanctioned by the modern dermatologist. Some women rub the skin smooth with pumice stone. Others prefer shaving with a safety razor—a plan that is perhaps to be approved when there is a thick downy growth of hairs too numerous to be removed by electrolysis.

The latest method of depilation before the profession is that effected by the x rays. Within nine months of the announcement of Professor Roentgen's discovery there were reported several cases of dermatitis to which I ventured to give the name of "focus-tube dermatitis" in July, 1897.<sup>1</sup>

The earliest note of shedding of hair which I have found recorded was by Mr. E. E. King of Toronto.<sup>2</sup> Since then many instances have been recorded, notably one by Professor Waymouth Reid, who lost the hair of the chest and face after four consecutive daily exposures of the trunk for 20, 40, 50, and 90 minutes respectively.<sup>3</sup> Before long the

Roentgen rays—or, rather, exposure to the focus tube—were applied for the depilation of hair. In at least one instance that came under my notice severe and extensive sloughing was caused by the exposure of a chin to the live tube. After a little time it was found that a short exposure of 10 or 15 minutes with the tube a few inches only from the surface of the skin affected the nutrition of the hair to such an extent that the hair became loose and fell out within a week or 10 days of the exposure. The hair bulbs, however, were clearly not destroyed, as the hairs were quickly reproduced. In one case reported by M. Barthelemy and M. Darien the hairs grew again in a guinea-pig that had been depilated 18 months previously by a prolonged exposure to the focus tube. Freund finds that the hair grows again on the face two months after depilation by that method.<sup>4</sup> By applying the rays, however, three or four times every six weeks it is possible, he says, to keep the face permanently hairless. Schiff has also worked on much the same lines. It is evident that any method depending on such repeated applications must be extremely tedious, and no results have hitherto been published which justify absolute success for any plan of the kind. At the same time, the application of the focus tube has to be made by skilled and cautious hands, otherwise the results may be disastrous. For one thing it is certain that the idiosyncrasies of individual patients differ greatly so far as the resulting dermatitis is concerned. Indeed, from my own observations it seemed to me long ago that the susceptibility of the individual worker might vary from day to day. The ideal exposure in depilation is that which suffices to cause the shedding of the hair with little or no apparent erythema or dermatitis. The part of the face around the area to be cleared should be protected with a mask of lead-foil. The drawbacks of depilation by the focus tube, then, are the risk of dermatitis (a small one under modern methods and in skilled hands) and, above all, the re-growth of the hair.

Electrolysis, on the other hand, is an effectual but tedious agent. It can hardly be applied in cases where there is a thick, close growth of hair, as each one has to be destroyed by the electrolysis needle. In the hands of the most skilful operator it is not always possible to direct the needle in the direction of the hair-follicle. Fortunately, from experiments conducted by Giovannini<sup>5</sup> it appears that destruction of the papilla may follow even though the needle has pierced the wall of the hair sac and cauterised the surrounding tissues. There is no need here to describe the details of this small operation. The needle is connected with the negative pole of a battery yielding from 1 to 1.5 milliampères, and the circuit is completed by pressing a sponge electrode saturated with warm salt water against the patient's skin. The circuit should not be completed until after the needle is inserted into the hair-follicle and the current should be broken before the needle is removed. The operator must insert the needle as nearly as possible in the direction of the hair-follicle. It should be kept in place for 20 or 30 seconds until little bubbles of gas appear at the point of insertion. After the removal of the needle, if the operation has been successful, the hair can be removed with gentle traction by a pair of forceps. The painfulness of the method forms one of the chief objections to electrolysis, and it varies much with the individual. To those who have the requisite patience and resolution, however, it offers the best chance of permanent removal of superfluous hairs.

Some time since it occurred to me that a combination of the two methods of focus-tube exposure and electrolysis might be of advantage. I have found the following method useful where the growth is not too thick. The exposure to the focus tube is made in the ordinary way and a week or ten days later, when the hair becomes loose, each hair is extracted and the electrolysis needle is passed into the follicle. This method means that a large number of electrolytic punctures must be made in a small area. However, with a little management the removal may be made to extend over a couple of days, and in that way it is possible to remove, so to speak, alternate hairs. Sometimes a second exposure to the focus-tube is needed before the hairs become loosened.

This combined method I have found useful in some cases, as it increases the chances of effectual cauterisation of the emptied hair-follicle. At the same time it shortens the

period of depilation, but, like pure electrolysis, it should not be undertaken unless the patient has enough resolution and patience to undergo the requisite treatment.

## A CASE OF SEPTICÆMIO PLAGUE IN A EUROPEAN.

By J. M. ATKINSON, M.B. LOND., D.P.H. CANTAB.,  
PRINCIPAL CIVIL MEDICAL OFFICER, HONG-KONG.

A BOY, aged 11 years, the son of a European inspector of police living at No. 8 police-station, was admitted to the Government Civil Hospital, Hong-Kong, on Sept. 9th, 1901, with the following history. He was quite well until the previous Saturday when he complained of abdominal pain. A medical man visited him on that day and prescribed castor oil; after taking this he vomited. On admission to the hospital at 9.30 A.M. his temperature was 102.4° F. He complained of pain in the abdomen and on examination the pain appeared to be chiefly in the right iliac fossa where there was on palpation a sense of resistance. His tongue was foul. His evening temperature was 102°. On examination of the blood no malarial parasites were found. On the 10th the pain was still the same and the patient was very drowsy. On the 11th a papular rash was noticed which was confined to the face, the neck, and the chest. In the evening he was delirious and he still complained of abdominal pain; there was some tympanites. As his temperature still kept up his blood was examined again, but no malarial parasites were found. On the 12th it was ascertained that during the night he had been vomiting bile-stained fluid tinged with blood. The stools were liquid and bile-stained, there was slight epistaxis, and the abdomen was still much distended and tender generally. A few malignant ring-formed malarial parasites were found on this day in the blood. On the 13th the patient seemed much worse. On examination there was evidently some fluid in the abdominal cavity. There was dulness in either flank which disappeared on change of position. For the preceding two days three grains of the bisulphate of quinine had been given hypodermically. The evening temperature was 102.8°, the pulse was 120, and there was constant vomiting. The specific gravity of the urine was 1030, with one-eighth albumin and no sugar; it gave an acid reaction. On the 14th at 6 A.M. the temperature was 105° and the patient was evidently sinking fast. He died at 2 P.M.

A necropsy was made on Sept. 15th at 9 A.M. Rigor mortis was well marked. On opening the abdomen there was some bloody ascitic fluid present. The small intestine was normal but distended. The cæcum was swollen, with hæmorrhagic extravasation into its walls, and there was a mass of enlarged hæmorrhagic glands (mæ-enteric) occupying the inner side of the cæcum and obstructing its lumen. There was also hæmorrhagic retro-peritoneal extravasation. On examining the enlarged gland tissue that and the spleen were found to be full of plague bacilli, which decolourised by Gram's method.

This case aptly shows what a perplexing disease plague is. The epidemic here has practically ceased for some weeks now, the number of cases reported from August 10th to Sept. 7th being 16, and this being the only European case during that time. The case was diagnosed as one of severe malarial colitis.

Hong-Kong.

**FRÖBEL AND CHILD STUDY ASSOCIATION.**—The second annual meeting of the Manchester Fröbel Association, with which the local branch of the British Association for Child Study is amalgamated for all meetings, was held on Oct. 18th. The report showed that there were 160 members as compared with 120 in the previous year, to which must be added 40 members of the Child Study branch. Professor Withers afterwards gave a lecture on "The Distinction between Work and Play." The educational uses of the latter were well illustrated, especially for the young child, for whom Fröbel more especially provided. Play in the child was described as the total self-activity of the child not as yet distinguished from work. A child was never so earnest as when playing, and he liked his play to be taken seriously.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### AGUE CONTRACTED IN A NON-MALARIOUS DISTRICT.

By J. LIONEL STRETTON, L.R.C.P. LOND., M.R.C.S. ENG.,  
SENIOR SURGEON TO THE KIDDERMINSTER INFIRMARY AND  
CHILDREN'S HOSPITAL.

THE mode of infection of ague has attracted so much notice of late that the following case will probably be of interest.

A woman, about 38 years of age, went to stay at Weston-super-Mare and whilst there she developed an attack of tonsillitis. During this illness she was visited by her brother who had lately returned from India where he had suffered from ague. On her return home she developed ague. Her description of the attacks is as follows: "I feel as if I was going to be ill; faintness and coldness, followed by severe shivering, during which I cannot hold anything. This cold feeling lasts about three hours and is followed by a feeling of extreme heat. My temperature is high; in one attack it was 106°. The hot stage lasts four or five hours and is accompanied by profuse perspiration which leaves me very weak and good for nothing. The attacks come on on alternate nights."

When I first saw the patient I had little doubt from her description of the attacks that she was suffering from ague, and I put her on five grains of salicylate of quinine three times a day which entirely checked them. A few weeks later when visiting in London she omitted her treatment and had a slight recurrence. At the present time, four months after her first attack, five grains of salicylate of quinine are sufficient to prevent the attacks.

In discussing with the patient the possible source of infection she naturally turned to the presence of her brother at a time when she was debilitated with an attack of tonsillitis and consequently in a susceptible condition. I explained to her how infection was often conveyed by mosquitoes and she at once informed me that she had a severe bite from an insect on the forehead during her brother's visit. There was no doubt whatever about this because it caused so much swelling that her sister inquired about it the next day. She could not remember the exact date of the bite, but she thought it was about a month before her first attack of ague.

I am not prepared to say what species of insect inflicted the wound on the forehead, but it appears to me probable that it was by that means that the poison was introduced. It may have been a mosquito secreted about the person of her brother—though as he had a new rig-out of clothes this was unlikely—or it may have been a stray member of the same species which had arrived through some other channel; but perhaps the more likely explanation is that some insect first attacked the brother and thus conveyed the *materies morbi* to the sister. If such a means of infection were to become common the presence in this country of ague subjects would be viewed with alarm.

Kidderminster.

#### A RAPID CASE OF DIABETES.

By R. E. H. WOODFORD, M.R.C.S. ENG., L.R.C.P. LOND.

A MAN, aged 23 years, came to me on Sept. 16th suffering from acne vulgaris of the face. A few of the spots were pustular. He was given boric acid ointment, and a week later the rash had much improved; he then complained of "feeling hot in his inside," but was not thirsty. He took a mixture containing bicarbonate of sodium and tincture of nux vomica for a week. On Sept. 30th his mother asked for more medicine and mentioned that he was thirsty. At my request he came to me the same day after he had done his usual work. He complained of being thirsty, but was confident that he had only been so for a few days. His bowels were confined and he felt weak. Examination revealed nothing except a raw beefy-looking tongue. His urine, however, contained sugar (no quantitative estimation was made),

with a specific gravity of 1037. On the following day he was admitted to Hitchin Infirmary under the care of Mr. R. Shillito who kindly sent me the following particulars: "He seemed rather dull and stupid when I saw him at 11 A.M. on Tuesday (Oct. 1st), but not having seen him before I naturally thought it was his normal condition. He had a dry parched tongue when I saw him in the afternoon and was, of course, very thirsty. He passed 171 ounces of urine on Wednesday but none after 6 A.M. on Thursday until shortly before his death at three in the afternoon. He was very sick and complained of cramp in his legs. The coma gradually increased from the time of his admission to his death. He had no convulsions. His bowels were very much constipated on admission and he complained of a good deal of abdominal pain, but they were freely relieved on Wednesday."

There is nothing of importance in his family history and he had had no severe illness. He indulged too freely in alcohol at times. It is noteworthy that he was able to work on the day previous to the onset of coma and he had been cycling on the Sunday before.

#### RICHMOND (SURREY) AND HESTON AND ISLEWORTH JOINT HOSPITALS. DOCKWELL SMALL-POX HOS- PITAL, HOUNSLOW.

TWO CASES OF CONFLUENT SMALL-POX AND ONE CASE OF  
DOUBTFUL MODIFIED SMALL-POX (VARIOLOID).

(Under the care of Dr. J. H. CROCKER.)

AT the present time, when small-pox is somewhat prevalent in London, the following interesting cases of the disease are of special value. The first case illustrates the severity of the disease in pregnancy and the second case the bad prognosis when the disease has been contracted just before birth. The third case demonstrates the very great difficulty there may be in diagnosing small-pox when it occurs in patients who have already been vaccinated. It is sometimes practically impossible to make a diagnosis without the aid of a history of infection and the subsequent progress of the case.

CASE 1.—A married woman, aged 39 years, was admitted into hospital on the evening of Sept. 25th, 1901. The patient had been confined of a male living child on the 22nd. She had noticed some spots on her face and body the day before her confinement, but she thought that it was possibly chicken-pox as two children in the same house had been suffering from this disease (?). The medical officer of health of Heston and Isleworth (Dr. E. J. Steegmann) saw the patient in consultation on the 25th and advised her immediate removal to the Dockwell Hospital. Dr. Crocker, together with Dr. Steegmann, saw the patient on the 26th and found well-marked small-pox in the vesicular stage confluent on the face, hands, arms, and chest. There was also evidence on the palate and buccal mucous membrane. There was no evidence of peritonitis; there were some lochia. The temperature was 105° F. The patient rapidly became worse, the lochia ceased, and she was semi-conscious on the 27th. On the 28th the eruption on the face was somewhat livid in colour, the pocks were all merged, and there were depressions of umbilication around the lips and the alae of the nose. The features were unrecognisable; the face, throat, and tongue were swollen. The hands and arms were swollen, the eruption on the extremities was coherent, giving an appearance of boiled sago grains. The patient was unconscious. On the 29th her general condition was worse. There was difficulty in swallowing, the tongue and lips were typhoid-like, and there were sordes on the teeth. There was some hæmorrhage

in the pustules on the face around the mouth. The eruption was pustular. The breathing was rapid. The patient died on the 30th at 2.25 P.M. As regards the temperature this gradually dropped from 105° at the commencement of the illness to 99° on the 30th.

CASE 2.—The infant child of the patient in the above case was admitted into the hospital along with his mother. He was vaccinated by Dr. Steegmann on Sept. 26th and at a later stage by Dr. Crocker. No result followed on either occasion. The child was, as already stated, born on the 22nd and he remained well until the 30th when he became feverish and vomited his milk. On Oct. 2nd a few spots were noticed on the face and on the 3rd there were several spots all over the face, body, and extremities, shotty in character to the touch. On the 4th the spots were larger and more profuse. On the 5th the eruption was confluent on the face and on the arms and hands, and on the 7th it was very shotty all over, being vesicular on the face. On the 9th the eruption was umbilicated and was getting pustular on the face; there was large vesicular eruption on the extremities. On the 11th a pustular eruption was present all over the face; there was some hæmorrhage in the pustules around the lips and the eruption was becoming pustular on the body. On the 12th the infant died at midnight. The temperature dropped from 103° F. at the commencement of the illness to subnormal on the day before death.

CASE 3.—A man, aged 25 years, was admitted into hospital on Sept. 29th. At the request of a general practitioner Dr. Crocker saw the patient before his removal. The history given was that on the previous day he had not felt well and that he had had slight pain in the back and had vomited. He had not been near any infectious disease as far as he was aware, but he had been "knocking about" London during the past month. On the morning of the 29th he did not feel well and he noticed that his face was covered with spots, so he sent for his medical attendant. At the time of Dr. Crocker's visit there was a profuse papular eruption all over the forehead and face; many discrete papules were present on the extremities and trunk, particularly on the back, over the shoulders, and extending up to and amongst the roots of the hair. The eruption was shotty to the touch. The temperature was 103° F. The patient had not been revaccinated, but there were two well-marked cicatrices (area about half an inch), the result of vaccination in infancy. The patient was revaccinated in four places by the public vaccinator and was removed to Dockwell Hospital and placed in the observation block on the evening of Sept. 29th. On the following day the eruption was more marked, being very shotty. The temperature was 102°. On Oct. 1st there were some spots on the face which were vesicular. The temperature was 101°. On the 3rd similar spots were observed on the back and chest. The temperature was 100°. On the 4th many of the spots on the face and elsewhere were disappearing, not having gone beyond the papular stage. The temperature was 99°. On the 5th there were slight brownish scabs on some of the pocks on the face and back; many others were drying up. The temperature was 99°. On the 7th one pock on the abdomen was large, umbilicated, and pustular; the others were drying up and disappearing. The temperature was 99°. On the 10th the face was nearly clear excepting for five or six slight superficial pittings, each slightly moist at the bottom. The pustule on the abdomen was scabbing. The temperature was normal. On the 12th there were a few scabs on the trunk; the remainder had dried up and almost disappeared. The temperature was normal. The patient was allowed to get up. In this case vaccination was for some days apparently without result, but slight papules appeared on three of the insertions on the fifth day. These three gradually developed and reached on the thirteenth day the stage usually arrived at in eight days. The condition on Oct. 12th was that one pock was of the size of a threepenny-piece and the other two were slightly smaller, a slight red zone being around each—that is, just in the stage when one in the old days took "matter" from the arm.

Remarks by Dr. CROCKER.—The patient in Case 1 had never been revaccinated, but she thought that she had been vaccinated when she was an infant. There was one doubtful cicatrix on the right arm, but owing to the eruption it was impossible to be certain.

As the eruption in Case 2 appeared 10 days after birth it is probable that the child contracted the disease in utero. Dr. Steegmann vaccinated two other patients from the same

lot of lymph as he used for this infant, and as these took well it is probable that the advanced stage of incubation of the disease prevented the vaccination from having any effect.

As regards Case 3 the question is, Was this a case of varioloid or of chicken-pox? There was no evidence of syphilis. Chicken-pox generally affects children; this patient was 25 years of age. In chicken-pox the temperature is very little raised in adults, as a rule, and quickly regains the normal; the temperature in this case was 103° to begin with and ended in a lysis, dropping about a degree each day to 99° and then, after remaining at this for three days, dropping to normal. In small-pox the rash generally comes out all at once in the same region, as it did in this case; whilst in chicken-pox the papular eruption comes out in a series of showers at daily or longer intervals, which did not occur in this case. In chicken-pox there is no, or very little, rash on the face as a rule; in this case the eruption was most profuse on the face, many, however, aborting in the papular stage. In one respect this rash simulated chicken-pox, being profuse over the shoulders and up to the roots of the hair at the back, a few spots being amongst the hairs. In two instances the papules formed crescents, one crescent being on the forehead and one on the abdomen, said to be characteristic of small-pox (Marson). Only one pock went the cycle of non-modified small-pox. Notwithstanding the fact that three out of the four vaccination insertions took, after some delay—which sometimes occurs with calf lymph under normal conditions—the case appears more like varioloid than chicken-pox.

### LEICESTER INFIRMARY.

#### TWO FATAL CASES OF PERFORATED DUODENAL ULCER.

(Under the care of the late Dr. J. ST. T. CLARKE and Mr. G. C. FRANKLIN.)

THE etiology of ulcer of the duodenum is very obscure. In some cases a duodenal ulcer is associated with ulceration of the stomach, and therefore it may be considered as probably produced by similar conditions. Against this view is the rarity of duodenal ulcer in women, though of the three cases recorded below two of the patients were of the female sex. Dr. Leo Dickinson<sup>1</sup> maintains that the women in whom it occurs are not young, but in both the female cases recorded below the age was 20 years. The association of duodenal ulcer with burns was first pointed out by Mr. Curling, but it is apparently rarer to-day than it was formerly. It has been suggested that the ulceration is the result of the excretion of septic substances absorbed from the large suppurating surfaces met with in burns and the occurrence of certain cases in which duodenal ulcer appears to have resulted from extensive internal suppuration favours this idea. Within recent years many cases have been recorded where hæmorrhage from the stomach and duodenum has occurred after operations, not necessarily on the abdomen—for instance, Eiselsberg<sup>2</sup> reported a case in which the hæmorrhage followed an operation for malignant disease of the tonsils and cervical glands. It is possible that there is some connexion between such cases as these and duodenal ulceration. For the notes of the following cases we are indebted to Dr. F. Bolton Carter.

CASE 1.—A young woman, aged 20 years, was admitted into the Leicester Infirmary on Jan. 5th, 1901, under the care of the late Dr. Clarke. The patient had had pain and vomiting after food for several months. 20 hours before admission she had been suddenly seized with severe pain in the abdomen and collapse. On admission she was pale and somewhat collapsed. Her abdomen was distended with a tympanitic note all over. There were some increased resistance and tenderness in the epigastric region. The abdomen was opened at once in the mid line above the umbilicus, and a perforated ulcer on the anterior wall of the stomach near the great curvature was found. This was stitched up with double rows of Lembert sutures. Another opening through the abdominal wall was made below the umbilicus, the peritoneal cavity was irrigated and wiped out, and drainage-tubes were inserted. The patient appeared to be doing extremely well for the next two days, and then vomiting commenced, with a great deal of pain in the abdomen. Signs of general peritonitis now became present and she died on Jan. 10th.

*Necropsy.*—On opening the abdomen post mortem it was found that there was general septic peritonitis. The stitched peritoneum over the gastric ulcer was firmly adherent, tearing apart with some difficulty. The appendix was healthy. On the anterior surface of the second part of the duodenum a perforation of about the size of a threepenny-piece was found. There were no other ulcers in the stomach or intestines.

CASE 2.—A man, aged 45 years, was admitted into Leicester Infirmary on Nov. 7th, 1900, with a history of having passed no urine for six days. He complained of slight pain in the right lumbar region. On the third day after admission, no urine having been passed, the right kidney was explored through the usual lumbar incision. The kidney was incised but no stone was found, and the hæmorrhage being severe the wound was plugged. On the next day the plugs were removed and a tube was inserted, urine coming freely through the wound. On the third day after the operation the patient passed seven ounces of urine per urethram. For the next seven days none was passed by the urethra, when 28 ounces were passed, and from this time he continued to pass a fair quantity daily. The quantity of urine from the wound now gradually decreased and the wound healed in about six weeks' time from the operation. Five weeks after the operation he had a severe rigor with a temperature of 105° F., and his temperature kept going up with rigors for about a week, during which time he complained of great pain on passing urine. His bladder was sounded for stone with negative result. His temperature now became normal and he was discharged on Jan. 1st, 1901, apparently well.

On June 1st he was readmitted under the care of Mr. Franklin with the history that eight days before he was suddenly seized with acute pain in the abdomen; he had been in bed since, had not vomited, but had had some diarrhoea, and had noticed that his abdomen had become swollen. There was no history of pain after food. On admission he had an anxious expression and his eyes were sunken. The pulse was 130 and small and the temperature was normal. The abdomen was very distended but not tender and it moved slightly during respiration. There was no liver dullness or dullness in the flanks. There was a tympanitic note all over. Perforative peritonitis being diagnosed, the abdomen was opened in the median line, mid-way between the pubes and the ensiform cartilage. The abdominal cavity was found to be full of fecal smelling pus, and the incision was then enlarged downwards and the appendix was sought for; this was found to be inflamed and was removed. The patient's condition being very bad the peritoneum was rapidly flushed out and the wound was closed, a drainage-tube being inserted. The patient died five hours after the operation.

*Necropsy.*—At the post-mortem examination a large perforated ulcer on the anterior wall of the first part of the duodenum was found. On opening the duodenum two other large ulcers were seen, one opposite the perforation involving all the coats except the serous, and the other a little lower down involving the mucous coat only. There were two small superficial ulcers in the stomach. The lower lobe of the left lung was collapsed. The right kidney had some scar-tissue from the old incision. There was no trace of calculi. Two small calculi were present in the renal substance of the left kidney.

*Remarks by Dr. BOLTON CARTER.*—I met with a case at the Royal Halifax Infirmary which might well be narrated in connexion with the two cases just recorded. A young woman, aged 20 years, was admitted into the Royal Halifax Infirmary on Oct. 29th, 1900, with a large tender fluctuating mass in the right iliac region. The temperature was 101.6° F. An abscess in connexion with the appendix being diagnosed Dr. E. West Symes, under whose care the patient was admitted, asked me to operate. An oblique incision internal to the right anterior superior iliac spine was made and a large quantity of foul-smelling pus was let out. The abscess cavity, which appeared to be well shut off from the general peritoneal cavity by adhesions, was flushed out and a cursory examination failing to discover the appendix, the wound was partially closed with silkworm-gut sutures and drained with a rubber tube. This was dressed twice daily and the patient's condition improved rapidly until Nov. 8th, when she complained of severe pain over the abdomen, not localised, and commenced to vomit. The pulse was 120 and she was rather collapsed. On the next day on dressing the wound some blood appeared to come from the upper and deeper part of it. Signs of general

<sup>1</sup> Transactions of the Pathological Society of London, 1895.

<sup>2</sup> Archiv für Klinische Chirurgie, 1899, vol. lix., part 4.

peritonitis rapidly supervened and the patient died on Nov. 10th. At the post-mortem examination it was found that there was well-marked general septic peritonitis. The appendix was in a sloughing condition, lying deeply over the pelvic brim, with no pus in its immediate neighbourhood. There was some blood-clot in the right lumbar region of the peritoneal cavity which appeared to have come from a perforated ulcer on the anterior surface of the second part of the duodenum. Some blood-clot was also present in the duodenum. There was no other ulceration in the duodenum, stomach, or intestines. There had been no history of previous gastric trouble.

In the case at the Royal Halifax Infirmary and in the first of the two cases at the Leicester Infirmary the patients were young women, whereas duodenal ulcer is more frequently met with in men. In both cases there was a septic condition in the peritoneal cavity which appeared to be doing well when the fatal complication occurred, and in both the duodenal perforation was situated in exactly the same position. In neither case was the perforation diagnosed, extension from the original seat of trouble being suspected, although in the first case it might have been; the cause of the hæmorrhage from the wound, however, was by no means obvious.

In Case 2 at the Leicester Infirmary it is difficult to connect the renal trouble for which this patient was first admitted in any way with the peritonitis causing his death. Was it possible that the abdominal mischief was due to an acute appendicitis, the ulceration in the duodenum and stomach being secondary to the septic peritoneal condition, as probable in the other two cases? It appears to me more likely that the duodenal perforation was the primary lesion and the inflamed condition of the appendix was due to the general peritonitis, the inflamed gut allowing organisms to escape through the walls and giving rise to the fecal odour of the pus. Another interesting point is the long duration, eight days, and the fact that the patient with his abdomen full of stinking pus *walked* into the surgery. The presence of the large quantity of fluid in the abdomen was completely masked by the great distension of the intestines. The complete absence of all tenderness and the definite movement of the abdomen during respiration are in my experience uncommon. The fact that no trace of calculi was found post mortem in the right kidney and that two were found in the left kidney makes one wonder whether the wrong kidney was explored at the first operation, and whether the pain on the right side was due to duodenal ulceration at that time. The man seemed quite positive that he had never had any pain after food, or other symptoms, at any time, although it is difficult to imagine that so much ulceration in the duodenum and stomach could have existed for any length of time without giving rise to symptoms. This appears to me rather in favour of the view that some, at all events, of the ulcers followed the septic condition of the peritoneum.

After looking through some of the literature on the subject I have been able to collect 59 published cases of perforated duodenal ulcer. In these cases 27 of the patients died without operation, the lesion being found post mortem. The remaining 32 cases were operated upon and 11 of the patients recovered. With the above three cases this gives a mortality of about 82.3 per cent.

## Medical Societies.

### MEDICAL SOCIETY OF LONDON.

#### *Typhoid Fever in South Africa.*

A MEETING of this society was held on Oct. 28th, Dr. W. H. ALLCHIN, the President, being in the chair.

Dr. A. ELLIOT and Dr. J. W. WASHBOURN communicated a paper upon Typhoid Fever in South Africa. They analysed the records of 262 cases which were admitted into the Imperial Yeomanry Hospital at Deelfontein and then compared these with Dr. T. B. Poole's cases at the Emergency Hospital at Maidstone during the epidemic of 1897 and with other statistics at the Metropolitan Asylums Board hospitals and the Johns Hopkins Hospital. Their object was to ascertain whether the type of fever in South Africa was the same as that occurring in England and America. The mortality of their cases was 13.7 per cent.—practically the same as that at the Metropolitan Asylums Board hospitals

during the year 1900, and that of the Worthing epidemic, but almost double that of the Maidstone epidemic and the Johns Hopkins Hospital cases. The incidence of relapse was 11 per cent.—practically the same as that of other statistics in England and America. They pointed out that early removal of the patients and improper feeding on the journey predisposed to relapse. The average interval between the end of the primary attack and the commencement of the relapse was 10.8 days, which appeared to be similar to that of other statistics. The longest interval between the end of the attack and relapse was 31 days. None of their cases which relapsed died. In 12 of their cases there was a history of a previous attack of enteric fever, an incidence of 4.5 per cent. Dr. Crombie had recorded an incidence of 6 per cent. amongst 150 officers who had been invalided from South Africa. The frequency of second attacks they attributed to the constant exposure to infection and to privation experienced by the patients. The mortality was 10.7 per cent. in 186 patients who had not been inoculated, while the mortality was 16 per cent. among 25 patients who had been inoculated. Adding together cases recorded at other hospitals the mortality among 120 cases inoculated was 7.4 per cent., and among 556 cases not inoculated 10.9 per cent. They did not consider that this difference pointed to any marked beneficial influence of inoculation. With regard to the influence of the inoculation upon the incidence of the disease, 59 of their staff were inoculated, of whom four contracted enteric fever. 25 were not inoculated, and of these four also contracted enteric fever. The four cases among the non-inoculated who contracted the disease came from among the dressers who were younger than the rest of the staff. Adding together various other statistics they found that of 224 persons inoculated the incidence of attack was 11.4 per cent.; and of 157 persons not inoculated the incidence was 14.6 per cent. From these figures they drew the conclusion that inoculation was not of any practical value in preventing the disease. They drew attention to the considerable risk of contracting enteric fever incurred by persons engaged in attending to the sick, the incidence of attack among them being 12.7 per cent. Hæmorrhage amounting to several ounces of blood occurred in 6.1 per cent. of their cases; the incidence corresponding about to the average. Half of their cases of hæmorrhage died, a much higher percentage than occurred in England or America. Phlebitis occurred in 5.6 per cent., the incidence at Maidstone being 3.8 per cent., in Caiger and Goodall's statistics 3.4 per cent., and in Osler's 1.9 per cent. The latest date of the appearance of phlebitis after the end of the attack was 30 days. Pneumonia occurred in 3.05 per cent. of the cases, the mortality being 50 per cent. Peritonitis, perforation, and parotitis occurred in about the usual proportion. There was constipation in 42.7 per cent. of cases. At Maidstone it occurred in 50 per cent. of the cases, at the Johns Hopkins Hospital in 34 per cent., and at the Edinburgh and East of Scotland Hospital in 37 per cent. It thus followed that constipation was more common both in South Africa and in England and America than was usually imagined. Rapid pulse was frequently observed in patients who had been previously exposed to fatigue, and there was often cardiac collapse quite out of proportion to the severity of the attack. In two cases of convulsions one was attributed to the administration of strychnine. Abdominal pain, sometimes so acute as to suggest perforation, occurred in several cases. In several cases there was difficulty in micturition at an early stage of the disease. Cases of appendicitis immediately preceding and immediately following enteric fever were recorded. A case of hepatitis was also described. Twenty-one cases associated with dysentery were recorded as arising during the attack or during convalescence and it was a symptom of serious signification, the mortality being 33.3 per cent. Rigors were observed in 11 cases; in two of these they were due to malaria, the parasite having been discovered in the blood. Arthritis was not uncommon during early convalescence. In a limited number of cases it was due to rheumatism. In the others it appeared to be allied to the arthritis occurring in scarlet fever. Other complications, such as tender toes, epistaxis, pericarditis, and eruptions of different kinds, were considered. The conclusions drawn by Dr. Elliot and Dr. Washbourn were that the type of disease in South Africa was practically the same as that met with in England and America, and that inoculation was of little practical value.

Dr. WILLIAM CAYLEY, referring to the causation of the

disease, said that although in this country almost all the epidemics were due to contamination of the water-supply it was clear that the means of infection in the tropics was frequently by other agents, such as dust and flies. It would be of interest to know if the clinical type of the disease varied with the different modes of infection. He congratulated Dr. Elliot and Dr. Washbourn on the low mortality. He considered that the evidence in favour of the immunity conferred by inoculation was sufficiently strong to make it desirable that it should continue to be used.

Professor A. E. WRIGHT (Netley), referring to the question of inoculation, said that although the general circumstances in South Africa were such that the results were not so favourable as those obtained from India, yet he was of opinion that some benefit was obtained from inoculation, however bad the general surroundings. He certainly considered that inoculation was advisable for India. In judging of the statistics there were several points to be taken into consideration. One of the most important of these was as to how long the patient had been inoculated. There was a negative phase which often followed an excessive dose, and he quoted the case of a man who had been inoculated three times and yet got typhoid fever. He himself had had three injections against Malta fever and yet he got the disease. It was certain also that the injection would only protect for a short time and he quoted statistics proving the value of being inoculated twice. He said that it was becoming evident that the dose had to be carefully adjusted and he now gave a small dose and repeated it, and in this way he avoided the negative phase. It was certain, also, that in some cases the injection afforded no protection, as was shown by the bactericidal property of the blood. He did not consider that age made any essential difference to the incidence of the disease.

Surgeon-General HENRY CAYLEY quoted statistics from the Scottish National Hospital, South Africa. He said that it was often difficult to obtain evidence from the soldiers as to whether they had been vaccinated or inoculated. Of the 54 persons who composed the first section of the hospital all but three were inoculated twice, two were inoculated once, and one not at all. Not one of the 54 got enteric fever though exposed to infection, and of these 25 were medical students between 19 and 24 years, the most susceptible age. In the second section, out of 102 persons 74 had been inoculated (some twice, some only once); of these five had enteric fever. Of these five, three had not been inoculated and two had been inoculated. Of 35 nurses 32 were inoculated twice, two were not inoculated, for they had recently had enteric fever, and one refused to be inoculated and she became infected with enteric fever. He certainly thought this evidence proved the value of inoculation for a certain time, possibly from five to six months. He believed also that inoculation made the attacks less severe. The cases of arthritis met with arose (he believed) rather in association with Malta fever than with enteric fever, and he thought the former fever occurred more frequently than was generally recognised. He said that the blood examination of the members of the first section of the hospital some months after they had been in South Africa still gave a high reaction, nearly all these having been inoculated twice; in the second section, however, which came out later, the reaction was poor, seeming to point to the fact that the inoculation had not been so efficiently carried out.

Dr. HOWARD TOOTH said that his figures, though small, were favourable to inoculation. He thought that the more severely the person reacted to the inoculation the less likely was he to be immune, and in Bloemfontein officers who had had severe reaction did not seem to be protected. With regard to immunity he classed individuals under three heads: (1) persons who were naturally immune; (2) persons who could be rendered immune by inoculation; and (3) persons on whom no immunity could be conferred. He believed that most individuals belonged to the second group.

Dr. H. D. ROLLESTON said that with regard to inoculation it was clear that it did not absolutely protect, but the statistics seemed to show that fatal results did not occur so frequently in the inoculated as in the uninoculated. It was important to take into consideration the interval elapsing between the inoculation and the attack of typhoid fever, and this had been on the average 38 weeks. Relapses and second attacks had been of common occurrence. He believed that there were several different strains of the typhoid bacillus and that an individual infected with two or more strains was not proof against other strains. He thought that the serum for inoculation should be prepared with mixed strains from

as many different sources as possible. He pointed out that although thrombosis was common yet there had been no case of pulmonary embolism.

Surgeon-General MUIR said that before accepting inoculation as of value far more statistics were needed. He thought that the source of enteric fever, though commonly water, was often conveyed by other means.

Dr. E. W. GOODALL said that with regard to causation too much stress had been laid upon the water-supply, and he was convinced that this was erroneous, for many cases arose in those attending the sick. All the complications which had been mentioned as occurring in South Africa after enteric fever he had seen in England, and he had also seen ulcerative colitis follow on an attack of typhoid fever.

Dr. WASHBOURN, in reply, said that although enteric fever could be contracted in different ways he could not say that the clinical type of the disease was different. The test to which inoculation had been put in South Africa had been severe, but it was in those cases where persons were frequently exposed to infection that it should be of greatest service; he did not consider that it should be resorted to in England where the sources of infection were comparatively few. Neither did he think that the inoculation should be lightly undertaken, for he had seen an officer laid up for three weeks with pyrexia after injection. He did not consider that the immunity of an individual could be estimated by the bactericidal capacity of his blood. He regarded the arthritis which occurred in the same light as the arthritis which occurred after scarlet fever. He suggested that the thrombosis which was of frequent occurrence might be due to the deficiency of salts in the food.

## CLINICAL SOCIETY OF LONDON.

### *Exhibition of Cases.*

A MEETING of this society was held on Oct. 25th, Mr. HOWARD MARSH, the President, being in the chair.

Dr. RAYNER BATTEN and Dr. LEONARD GUTHRIE showed a boy, aged 12 years, with Right-sided Hemiparesis and Atrophy of the Left Optic Disc. He had fractured his left femur in October, 1900, and whilst laid up had had a doubtful attack of acute rheumatism. In February, 1901, he noticed weakness (gradual) of the right arm and of the legs, with difficulty in writing and in walking. When seen on April 30th, weakness, ataxy, and intention tremors were noted in the right arm. The right leg was wasted, the knee-jerk was exaggerated, ankle clonus was marked, and a typical Babinski's plantar reflex was present. Sensation was normal. A faint presystolic bruit was present. The veins of left optic disc were engorged, but there was no swelling of the disc. On June 28th the condition of the discs was as follows. The left optic disc was pale and excavated. The cribriform plate was exposed at the bottom of the excavation. The disc was not filled in or opaque. There was no blurring of vessels or of the margins of the optic disc. There was a well-marked central scotoma for white (no colour perception). The retina in the macular area and up to the optic disc showed signs of disturbance and a number of fine white dots. The veins were somewhat large, dark, and tense. The right optic disc was normal. No hemianopsia was present. On Oct. 1st the paresis was much improved and the vision of the left eye was very slightly impaired. It was suggested that the patient might have had thrombosis in the neighbourhood of the left motor tract with retro-bulbar neuritis of the left optic nerve, or the condition might be due to early disseminated sclerosis.—Dr. F. E. BATTEN said that he did not think the condition was due to disseminated sclerosis. He had seen a similar case in a female, aged 25 years, who suddenly became hemiplegic on the right side with aphasia and complete blindness in the left eye. The patient died some two years later and at the necropsy it was found that there was softening in the distribution of the left middle cerebral artery and the left optic nerve was completely degenerated owing to thrombosis of the vessel supplying this region.—Dr. BATTEN, in reply, said that he thought the presence of a central scotoma pointed to a vascular lesion.—Dr. GUTHRIE said that the remarkable recovery which the boy had made seemed to him to be in favour of a disseminated sclerosis rather than a vascular lesion.

Dr. J. P. PARKINSON showed a case of Glénard's Disease.

The patient, a married woman, aged 40 years, had had five children. She complained of symptoms due to stenosis and regurgitation of the mitral valve and cardiac dilatation. The abdomen was very large and flabby from relaxation of the muscles of the abdominal wall. When lying on the back the lower limit of the liver could be felt a finger's-breadth below the level of the umbilicus and its dullness above extended to the costal margin, but in the erect position it fell to a much lower level. It could be freely moved about between the two hands. The spleen was also felt to be somewhat enlarged, prolapsed, and moveable. The right kidney could be easily felt as a moveable mass below the right limit of the liver, from whence it could be pushed back into the loin. The left kidney appeared to be normal in position. The stomach seemed to lie somewhat below its usual level and to be slightly enlarged. For a week in the middle of June the patient suffered from a constant pain in the right loin which extended from thence to the anterior superior iliac spine, and during this period the urine, which previously had contained only a trace of albumin, diminished to half its usual amount and contained two-fifths of albumin. When the pain ceased the albumin, and for a few days the amount of urine, increased to three or four pints daily. This temporary interference with the functions of the kidney was the only symptom referable to the large amount of visceropertosis present.

Dr. SEYMOUR TAYLOR showed a case of Congenital Absence of both Clavicles. The patient was a man, aged 20 years, in whom both clavicles were incompletely developed. On each side the sternal ends, with the attachments of the sterno-mastoid muscles thereto, could be felt, and there appeared to be some attempt at development towards the acromial end. The intervening space was occupied by what appeared to be fibrous structure, possibly representing the costo-coracoid membrane. The upper limbs were not impeded in their various movements; indeed, the patient had no previous knowledge of his defects. On the other hand, he could throw a ball and play cricket as well as most youths. Both shoulders could be so far approximated to the middle line that the eminences of the deltoid muscles could be made to touch each other. The condition thus approached that of the carnivora.

Mr. F. C. WALLIS showed a case of Hydrops Articulii in the Knee-joint of an old man who was the subject of well-marked Osteo-arthritis. The ligamentum patellæ had been ruptured; previously to that the patella had been twice fractured; it could now be felt some distance up the thigh. In spite of this condition the man was able to get about with the aid of a stick. The large fluid swelling in front of the joint had been aspirated three times and pressure had been applied. This had had no effect in reducing the fluid. The comparative ease with which the man got about with so disorganised a joint was no doubt helped by this fluid condition of the joint cavity.

Mr. WALLIS also showed a case of Acute Intussusception in a child, aged seven months (ileo-cæcal variety) successfully treated by operation. This patient was admitted to the Metropolitan Hospital on July 21st with somewhat obscure symptoms of intestinal obstruction. The operation was performed 33 hours after the first onset. An incision in the upper part of the right semilunar line was made and the abdomen was opened. The intussusception, which occupied the situation of the hepatic flexure of the colon, was drawn out of the incision and by gentle traction and pressure it was gradually reduced. The intussuscepted gut was seven inches long, quite collapsed, somewhat congested, and thickened. After reduction the intestine was returned to the abdomen and the abdominal incisions were closed by one row of silkworm-gut sutures. The operation lasted for 20 minutes. The bowels acted next day. Recovery was uninterrupted except that the infant was unable to digest any peptonised or other milk, but when the mother recommenced to feed the child this trouble ceased, and the little patient was discharged on August 8th quite well.—Mr. A. E. BARKER suggested that Mr. Wallis should describe the stages of the operation, for he considered it of great importance that only a small opening into the abdomen should be made and the gut manipulated with the first finger in the abdomen and the thumb on the abdominal wall.—

Mr. WALLIS, in reply, said that in this case it had been impossible to reduce the intussusception within the abdomen and therefore it had to be brought out and it was then easily reduced. One of the most interesting features of the case was, however, the congestion which was present; this was

so extreme that had he not on a previous occasion seen a similar condition in a child who made a good recovery he would have thought it hopeless to return the gut.

Mr. H. B. ROBINSON showed a case of Leontiasis Ossea, (? "Henpuye"). The patient, a man, aged 26 years, had very hard, almost symmetrical swellings on the nasal bones and adjacent parts of the superior maxilla; the skin was not involved. The nasal chambers were almost completely blocked, the turbinates being pushed towards the septum. The swelling first appeared on the left side in 1897 and progressed slowly. There was no pain and no watering of the eyes. There was no history of syphilis. He had been in South Africa since the lesions appeared. The remarkable feature of the case was its strong likeness to "henpuye" or "dog-nose" of Cape Coast Colony.—Mr. CHARTERS SYMONDS suggested that the masses should be removed by operation. He referred to a similar case of about from eight to 10 years' duration, in which he had made the usual incision for removal of the upper jaw and chiselled away the bone and opened into the post-nasal space. The patient made a good recovery and there was no recurrence. He mentioned another case in which improvement had taken place.—Mr. ANTHONY A. BOWLBY said that under the heading "Leontiasis Ossea" three somewhat distinct conditions were described—firstly, a condition in which many bones were affected; secondly, a condition limited to the upper jaw; and thirdly, a localised condition closely allied to the "henpuye" which was met with in South Africa.—Mr. C. R. KEETLEY said that he had seen a patient with a similar condition which was unilateral. This he had removed, with the result that the patient made a good recovery and had had no recurrence of the growth. In another case of a young girl he had also removed the bone by an incision within the mouth, and that patient also made a good recovery with no deformity.—Mr. ROBINSON, in reply, agreed with Mr. Bowlby with regard to the nomenclature of the disease, and considered that an operation was certainly advisable in this case.

Mr. CHARTERS SYMONDS showed a case of Pulsating Tumour of the Sacrum. The patient, a man, aged 65 years, went to Guy's Hospital complaining of pain in the sacrum. On rectal examination a pulsating tumour could be felt high up covering the whole width of the sacrum, and reaching rather further to the right. The pulsation could be controlled by compression of the aorta. Through the sacrum a loud systolic bruit could be heard. The patient had also outward displacement of the left eyeball due to a formation (growth?) in the inner side. From the nose he had a polypus removed a year or more ago. It was suggested that pulsating tumour was a growth secondary to that in the ethmoid.—Mr. CECIL LEAF asked if there was any relation between the polypus removed from the nose and the growth.—Mr. WALLIS asked about the duration of the condition and suggested the possibility of the condition being a naevoid one.—Mr. BARKER suggested that the patient should be examined with a speculum. He recalled a case in a man, aged 40 years, who had very extensive naevoid growth in the rectum. He had had one or two attacks of hæmorrhage as a child. He died from hæmorrhage from the rectum.—Mr. CHARTERS SYMONDS, in reply, said that the ocular condition had been present for nearly a year. There had been an error in saying that a polypus had been removed from the nose. There had been a suppurative condition and that had been treated. The rectal examination did not suggest a naevoid condition. He thought it most likely that the condition was either a pulsating sarcoma or an aneurysm.

Mr. CHARTERS SYMONDS also showed a case of Syphilitic Myositis of the Extensor Cruris. This patient was exhibited last session. He was again exhibited in fulfilment of a request made at that time. Doubt was expressed as to the nature of the case, some thinking the condition to be a new growth. In the interval rapid improvement had taken place, preceded by involvement of the skin. The patient was unable to submit to the treatment of rest and for a time was without medicinal treatment. When he returned there were effusion into the knee and signs of advancing disease, and the skin was broken in several places. Large doses of iodide produced rapid improvement, so that the diagnosis could no longer be doubtful.

Dr. H. E. SYMES THOMPSON showed a case of Arthropathy in a case of Bronchiectasis. The patient, a single woman, aged 26 years, first showed symptoms of chronic bronchitis about 18 months ago, the sputum being offensive from the first. Twelve months ago the sputum became more

offensive and more copious, and about this time the ankle-joints first became affected. Subsequently the wrists and knees were involved. Both wrists were swollen, stiff, and tender. The fingers were also somewhat swollen. There was much muscular atrophy. The knees were slightly swollen and contained a little fluid. The ankles were enlarged but were not tender. Physical signs of bronchiectasis were well marked at the left base. The sputum, which formerly was very offensive, had now no foetid odour and the quantity had greatly diminished.—Mr. BOWLEY pointed out that the joint condition in these patients was almost certainly due to the septic infection from the cavities in the lung. He considered that these cases were closely allied to the rheumatoid arthritis which had been described in children.—Dr. SEYMOUR TAYLOR asked under what treatment the foetid sputum had been improved.—Mr. WALLIS said that he had observed synovitis in a case of ulceration of the rectum and that as soon as the ulceration was cured the joints also recovered. He referred to the association of joint trouble with appendicitis, some cases having been recorded by Dr. H. D. Rolleston.—Mr. CHARTERS SYMONDS said that he had seen several cases of chronic suppuration and infection of joints and that as soon as the suppuration was cured the joint condition also cleared up.—Dr. SYMES THOMPSON said, in reply, that the treatment of the case had been by creasote and general measures. He thought that at present the balance of evidence was against operation in these cases; it had been tried, but on the whole with unfavourable results.

## LIVERPOOL MEDICAL INSTITUTION.

### *Aneurysmal Varix of the Femoral Artery and Vein.—The Personal Factor in Tuberculosis.*

THE first ordinary meeting of the session of this society was held on Oct. 24th, Mr. EDGAR A. BROWNE, the President, being in the chair.

Dr. R. C. DUN showed a patient suffering from Aneurysmal Varix of the Femoral Artery and Vein in the Upper Part of Scarpa's Triangle on the left side resulting from a Mauser bullet-wound. Very severe hæmorrhage had immediately followed the receipt of the injury. The communication between the artery and vein had apparently developed on the third day after the wound was inflicted, as indicated by the supervention of pulsation and thrill over the vessels. For the past year the patient had been doing full work as a tailor, suffering comparatively little inconvenience. There was no distinct tumour in Scarpa's triangle, merely an ill-defined swelling. Expansive pulsation and marked thrill were present, with a very loud rumbling bruit resembling the noise heard when travelling in a train passing through a tunnel. There was no œdema of the limb below or varicosity of veins. The pulsation and thrill gave no inconvenience to the patient after long standing or walking and the limb was readily tired. It was not considered advisable to attempt any operative interference.—Mr. RUSHTON PARKER referred to a formidable case of the kind operated on by Professor Lister in Edinburgh over 20 years ago. The femoral artery was tied above and below the aperture and the much dilated vein was stitched up with antiseptic catgut and its channel was preserved. Though much blood was lost in a prolonged operation the patient recovered with a useful limb.—Mr. GEORGE HAMILTON mentioned several cases of Ring Stricture of the Sigmoid Flexure which he had previously brought before the society and in which the patients were still alive and well. Stress was laid first on the fact that carcinoma of the intestine was not nearly such a malignant disease as carcinoma elsewhere; and secondly, that an operation for removal was best conducted in two stages, no attempt being made to unite the divided bowel at the primary operation. A very unusual case was related of a man who was 68 years of age and who suffered from a carcinoma of the sigmoid flexure which had become (owing to a long mesocolon) attached to about the middle of the transverse colon. In order to remove this growth it was found necessary to take away 16 inches of large bowel. The man had made an admirable recovery. Mr. Hamilton made some further remarks on the advisability of recognising these ring strictures before much intestinal obstruction occurred.—Mr. RUSHTON PARKER agreed with Mr. Hamilton that in a case of this kind it was the best practice to tie tubes in the out ends of the gut and bring them out of the wound,

reserving to a future operation any attempt that might be made to re-unite the gut.

Sir DYCE DUCKWORTH read a paper on the Personal Factor in Tuberculosis.<sup>1</sup> He pointed out how at the present time the whole art of medicine, and in particular the science of pathology, was dominated by bacteriological ideas. Amidst the enthusiasm with which these momentous discoveries in this field had been received he could not but feel that some important although older doctrines had been lost sight of. The doctrine of the diatheses received little or no attention in these days, but bacteriology had not done away with these textural conditions, although it had temporarily overshadowed the recognition of them. The modern doctrine was laid down that "scrofula was tuberculosis." This Sir Dyce Duckworth absolutely denied, and he maintained that it was possible to be scrofulous throughout life without becoming tuberculous. The essential character of scrofula was a textural vulnerability to irritation of all kinds, and especially to tuberculous invasion. A protest was made against the modern idea of "curing" tuberculosis. All they could do was to place the patient in conditions favourable to an arrest of the process. No malady was so often arrested as tuberculosis, but none was more ready to relapse at any period within the lifetime of the patient. A better comprehension of the textural proclivities of the individual might enable them to frame a sounder prognosis in respect of liability to relapse after the occurrence of an arrest. More than this they could not do. In any case, bacteriology was not the "be all" and "end all" of clinical medicine, as it was so commonly supposed to be.—Dr. T. R. GLYNN considered that Sir Dyce Duckworth's remarks on the importance of recognising the part played by the constitution of the host in the development of tuberculosis were fully warranted owing to the attitude of certain physicians at the present time. He had the opportunity of seeing a number of medical reports on the health of applicants for insurance and had noted that some medical examiners in cases where there was a history of phthisis in a family made such remarks as this: "Some of the relatives have died from tuberculosis, but this affection is no longer considered hereditary, and it is not necessary to charge an extra." The pathologist, in his inoculation experiments, studied only one aspect in the etiology of tuberculosis, but he could not understand how the physician could fail to recognise the importance of the other aspect—predisposition, hereditary or acquired. He thought that, for the most part, what was formerly known as the strumous diathesis would now be recognised as degeneracy.—Dr. WILLIAM CARTER agreed that it was as necessary to consider the soil as the seed, but he believed that most, if not all, medical men took this view. Facts bearing on the importance of the nature of the soil were too patent to be mistaken, such, for example, as tuberculosis ceasing after small-pox, &c., the different order in which structures were attacked in the young as compared with the aged, the greater degree of susceptibility of the coloured races, &c. In every case it seemed to be a struggle between destructive and defensive forces, for the probability was that there was no absolute immunity in any individual of any race. It seemed probable, also, that the bacillus tuberculosis could grow on different media and produce different toxins accordingly. The importance not only of diathesis but of what was termed "temperament" was wisely recognised by their forefathers, and a rough but practically useful classification into sanguineous, nervous, lymphatic, &c., persons, the reaction of whose tissues both to disease and remedies was the outcome of their observations. In this kind of knowledge they had probably declined. Cures in an absolute sense must be very rare. A curious fact was, perhaps, worth mentioning as bearing on the supposed reliance placed by the professional mind in bacilli destroyers as against soil modifiers—viz., that though Koch's demonstration of the cause of tuberculosis was made in 1881 there was scarcely a single important addition made to the official anti-microbic drugs since the Pharmacopœia of 1867, which looked as though the professional judgment of the nation relied more on supporting the patient against the attack of the bacillus than on directly destroying the bacillus after its invasion of the organism.—Dr. W. B. WARRINGTON recognised the greater vulnerability of some to tuberculous disease arising either from inherited defects or acquired conditions of lowered vitality.

<sup>1</sup> We propose to publish this paper in full in an early issue of THE LANCET.

He considered, however, that it must be a very difficult task to point out such specific features in individual physiognomy as would enable an observer to state with reasonable probability the individuals who were the more liable to tuberculosis. Similarly he considered that it would be difficult to predict of several individuals, previously healthy and whose family history was unknown, which individual was on exposure to cold and fatigue most liable to rheumatic fever. The pneumonia bacillus inhabiting the mouth of a healthy person might be as virulent as that found in one suffering from the disease. There must, therefore, have been some change in the host, but this change could not be recognised. The statement he would emphasise was that the proof of a diathesis was often the proof of a disease.—Dr. THOMAS HARRIS (Manchester) scarcely thought that the modern pathologist so completely ignored the personal equation of the suitability of soil in favouring or retarding the development of tuberculosis as Sir Dyce Duckworth inferred. There could be no reasonable doubt that the suitability or otherwise of the soil not only affected the tendency to the development of tuberculous foci in the first instance but also played a great part in the subsequent progress of such foci. The favourable results following the modern treatment of tuberculosis in open-air sanatoria were doubtless due to the rendering of the human organism a less suitable soil for the progress of the lesion and resulted in many cases in an arrest of the disease. It was quite right to use the term "arrest" in reference to such cases and to avoid the term "cured."—Dr. R. J. M. BUCHANAN and Dr. J. BARR also spoke, and Sir DYCE DUCKWORTH replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—The opening meeting of the session of this society was held on Oct. 18th, Dr. A. G. Barrs, the President, being in the chair.—The President delivered an opening address on Some Points in Medical Practice.—Dr. Christy Wilson (Doncaster) read a short paper on the Montana Sanatorium in the Rhone Valley, showing in the first place lime-light pictures of Nordrach-upon-Mendip and Altadore, in County Wicklow. Montana, near Sierre, was chosen as the site of a large sanatorium by a number of the leading physicians in Switzerland and the entire control was placed in the hands of Dr. Stephani. The altitude (5000 feet), the small rainfall, the great amount of sunshine, the almost total absence of fogs, the complete shelter from the north and east by mountain ridges covered with an immense pine forest, the spacious verandahs, the generous diet, the lakes for figure-skating, the lovely walks in the park and the forest, all combined to give the unfortunate victims of tuberculosis an excellent prospect of cure. Disinfection of the rooms by scrubbing with sublimate and by formaldehyde vapour under high pressure was carried out rigorously. The hope was expressed that ere long every case of pulmonary tuberculosis would be notified and isolated in a sanatorium.—The President made some observations upon the subject.—Mr. Secker Walker read a paper on the Advantages of the Complete Operation as devised by Mr. Ballance for Mastoid Disease and Chronic Otorrhoea over the Older Methods. The operation was described in detail. Its special advantages were given as follows. The whole seat of the disease in the cavities of the temporal bone was exposed to clear view and the disease could be entirely removed. By the free cutting away of bone and the amount of room thus secured it was not difficult to keep away from what might be termed dangerous areas, or they might be better approached with caution. At the end of a fortnight the freshly-cut surface of the bone, now vascularised, was covered with a large epithelial graft which lined the whole cavity and by immediate healing prevented the recurrence of the disease. The period of treatment was much less, from four to six weeks, instead of as many months. The results of the older methods were so uncertain that surgeons hesitated to advise operation for chronic otorrhoea and only operated for obvious mastoid disease. With this operation it was possible to speak with something approaching certainty of success, while the results on the power of hearing were distinctly good.—Dr. A. L. WHITEHEAD had performed the operation according to Ballance's method a number of times and he thoroughly agreed with Mr. Walker as to the great advantages presented by this method over all others. He preferred to use the chisel to enter the antrum and the burr to enlarge the cavity and to smooth the walls. The importance of securing a healthy condition of

the naso-pharynx was mentioned so as to prevent reinfection through the Eustachian tube. The practical certainty of effecting a cure by this operation was so great that no case of chronic otorrhoea should be allowed to go on uncured.—Mr. E. Ward and Dr. James Kerr also took part in the discussion and Mr. Walker replied.—The following cases, pathological specimens, &c., were shown. Dr. J. B. Hellier: (1) A Uterus Extirpated for Intractable Prolaps; (2) a Double Hydro-salpinx; (3) (with Mr. R. Smalles) a Dermoid Ovarian Cyst removed in the Fifth Month of Pregnancy; and (4) (with Mr. B. Wainman) Ruptured Tubal Gestation treated by Abdominal Section.—Mr. H. Littlewood: (1) Three Specimens of Ectopic Gestation; (2) Loose Cartilage removed from the Elbow-joint; and (3) an Implantation Cyst from the Finger.—Dr. A. G. Barrs: (1) Specimens from a case of Hodgkin's Disease; and (2) a case of Hysteria in the Male.—Mr. B. G. A. Moynihan: (1) A series of specimens from Operations for Recurrent Appendicitis; (2) a Vermiform Appendix transfixed by a pin which had been swallowed 14 days before operation; (3) a Part of the Ileum, the Cæcum, the Ascending Colon, and a Portion of the Transverse Colon removed for Carcinoma; (4) the Sigmoid Flexure removed for Chronic Recurring Volvulus; (5) Malignant Stricture excised from the Sigmoid; and (6) specimens from cases of Excision of the Rectum by Kraske's method.—Dr. T. Churton: Two cases of Nervous Disease (Myoclonus and Disseminated Sclerosis) treated by Subcutaneous Injection of Curare.—Dr. Whitehead: A specimen of Rhinolith; and (2) a case of Microtia.—Mr. Mayo Robson: (1) Multiple Tuberculous Constrictions in the Small Intestine, Enterectomy for Intestinal Obstruction; (2) Almost Complete Gastrectomy, recovery; and (3) Two Partial Gastrectomies, recovery.—Dr. C. M. Chadwick: A case of Rheumatoid Arthritis in a Child.—Mr. Lawford Knaggs: Ectopic Gestation.—Dr. E. F. Trevelyan: A Part of a Brain showing Multiple Gummata.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The first meeting of the session of this society was held at the Guildhall, Windsor, on Oct. 23rd, the President, Mr. W. B. Holderness, J.P., being in the chair.—Seven microscopical preparations illustrating the Minute Anatomy of the Appendix under Healthy and Pathological Conditions were exhibited, as well as two wet specimens showing the naked-eye appearances of the same, the whole being lent by Dr. G. Leslie Eastes of the Laboratory of Clinical Pathology, Queen Anne-street, W.—Dr. W. F. Lloyd showed a specimen of a Cæcum and Ruptured Appendix from a case of perforating appendicitis in a boy, aged 10 years.—Mr. Noble Smith showed some excellent Photographs illustrating the effect of treatment upon various deformities, e.g., wry-neck, spinal curvature, &c.—Dr. E. S. Norris exhibited a patient suffering from Multiple Growths, presumably sarcomatous in nature. There were great protrusion of the eyeballs and almost total blindness.—Dr. Lloyd showed a boy suffering from Enlarged Glands and Anæmia. The case had improved greatly under arsenic, and a blood-film was shown which indicated that the condition was not caused by Hodgkin's disease.—Dr. G. E. Hale showed: (1) A well-marked case of Fibroid Phthisis affecting mainly the right side in which the heart was drawn considerably over to the right; and (2) a young woman with a Tumour in the Right Lumbar Region of the Abdomen. It was thought to be a cyst of the right kidney.—Mr. A. Marmaduke Sheild read a paper entitled, "When to Operate in Appendicitis." The paper commenced by quoting certain varieties of the disease where operative methods seemed the sole hope, these being fulminating or gangrenous appendicitis and perforative appendicitis with general septic peritonitis. Stress was laid on the deceptive and dangerous nature of these cases and on the great importance of their early recognition. Appendicitis with local inflammatory mischief was next touched upon and here Mr. Sheild said that the rules of practice were not so clear. The considerations for surgical and medical treatment in these cases were mentioned and conclusions were drawn. The formation of abscess always calling for incision the indications of pus formation were pointed out. Under so-called recurrent appendicitis the medical and surgical aspects of the disease were noticed. The paper specially dealt with these cases as met with in private practice, the difficulties of the medical attendant in the question of morphia administration and the attitude of friends and relatives being entered into. Treatment, owing to time, could not be more than touched upon, but a method devised

by Mr. Sheild of introducing saline purgatives into the large intestine was described.—A discussion followed in which Dr. Norris (Eton), Mr. Arnold Thomson (Maidenhead), Dr. Francis Hawkins (Reading), Mr. R. S. Charsley (Slough), Mr. Noble Smith (London), and Mr. E. W. Adams (Slough) took part, and Mr. Sheild having replied the proceedings terminated with a vote of thanks to Mr. Sheild for his very lucid and instructive address.

**SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.**—A meeting of this society was held at the Hospital for Sick Children, Great Ormond-street, W.C., on Oct. 18th, Dr. D. B. Lees being in the chair.—Dr. Fennell showed, for Dr. Garrod, a case of Cerebral Diplegia. Ataxy was associated with spasticity, a fact which was considered to suggest that not only the cerebrum but the cerebellum also was affected. Retinitis pigmentosa was present, a point of interest in connexion with the etiology of cerebral diplegia and the suggestion of its connexion with syphilis.—Dr. Poynton, Dr. Hawthorne, and Mr. Carre-Smith commented upon the case, and Mr. G. Pernet remarked that De Amicis of Rio de Janeiro had placed upon record several cases in which there was undoubted syphilis in one or both parents of children with retinitis pigmentosa.—Mr. H. S. Collier showed an infant, aged three months, the subject of Congenital Deformity of the Left Shoulder Girdle and Spine of the type described by Willett and Walsham.—Dr. Lees showed a case of Enlargement of the Heart the result of Rheumatism. Thrombosis of the right brachial and jugular veins had been present.—Dr. Lees also showed a case of Arsenical Neuritis caused by Liquor Arsenicalis used in the treatment of chorea. A dose of 15 minims had been given by a medical man for five weeks.—Dr. Hawthorne and Dr. W. C. Chaffey spoke upon the case.—Dr. Hutchison showed a case of Double Facial Paralysis following Ear Disease which had quickly recovered after both mastoids had been operated upon.—Dr. Lees and Dr. Sansom commented upon the case.—Dr. Theodore Fisher showed a Heart from a child, aged 15 months, in which the mitral orifice was extremely stenosed. Marked symptoms pointing to disease of the heart had been present from the time of birth. A heart was also shown from a child, aged four and a half months, in which the segments of the aortic valve were much thickened and adherent to one another. In the first case no history of rheumatism could be obtained in the mother, but in the second about three months before the birth of the child there had been pain and swelling of the left knee.—Dr. Sansom remarked upon the fact that such cases were not malformations in the strict sense of the word but the consequences of intra-uterine endocarditis.—Dr. Chaffey read a paper on a case of Enlarged Spleen associated with the Blood Changes of Pernicious Anæmia. He thought the case was one of pseudo-leukæmia which had terminated with destructive blood-changes.

**BRADFORD MEDICO-CHIRURGICAL SOCIETY.**—The inaugural meeting of the present session of this society was held on Oct. 15th, Dr. R. Honeyburne, the President, being in the chair.—Cases, Pathological Specimens, Photographs, and Surgical Instruments were shown by Dr. Arnold Evans, Dr. A. Bronner, Mr. J. B. Hall, Dr. James Kerr, and Mr. William Horrocks.—The President read a paper on the Diagnosis and Treatment of Diphtheria. He justified the choice of this disease as the subject of an inaugural address because they knew its cause and symptoms, the manner of their production, and its cure and prophylaxis. Further, it appeared from various health reports that the disease, which was rare in the West Riding cities until recent years, appeared to be on the increase and had assumed alarming proportions in Leeds and Sheffield. The death-rate in Britain from diphtheria compared very favourably with that obtaining in continental and American cities. The Klebs-Löffler bacillus fulfilled the three conditions necessary to prove that it was the *causa causans* of diphtheria: (1) it was universally present in diphtheritic membrane; (2) it could be cultivated outside the body and inoculation of the pure culture into cats caused symptoms identical with those of the disease in man; and (3) accidental inoculation of human beings with the pure culture had occurred and the disease had been produced in a virulent form. Nothing was known regarding the life-history of the bacillus outside the body (if it had such a separate existence). The only domestic animal naturally susceptible was the cat, and instances of infection from that source were not common;

so that the only known factors relating to the spread of the disease were the age of the patient and the season of the year. Improved sanitary conditions which had done so much to mitigate enteric fever had had no effect on diphtheria, which had increased rather than diminished both in range and virulence during the last 20 or 30 years. It was probable that the infection was often conveyed by apparently healthy persons who yet harboured virulent bacilli in their mucous membranes. The cardinal rules of treatment were: (1) inject antitoxin serum early; and (2) inject an efficient dose. The use of antitoxin as a prophylactic was only of very limited application, but might be used, perhaps, with advantage in schools to prevent the immediate spread of an outbreak, as it would confer immunity for something like three weeks.—The paper was followed by a discussion in which several members took part.

**SOCIETY OF MEDICAL OFFICERS OF HEALTH.**—A meeting of this society was held on Oct. 25th when a Presidential Address was delivered by Mr. A. Wynter Blyth on Ventilation, the substance of which will be found at p. 1180.—In the discussion which at Mr. Wynter Blyth's express desire followed the address Dr. Gwynn made some remarks on the defective ventilation of places of worship.—Dr. McVail expressed his conviction that Professor De Chaumont's standard—2 parts per 10,000 of organic CO<sub>2</sub>, or 6 parts in all—was fixed too high, since the outer air in towns frequently contained that amount, and it was obviously impossible to have a purer air in any occupied room. When the apartments and its occupants were clean he was certain that four parts of organic CO<sub>2</sub> might be present without any perceptible odour or closeness. He had found it so in a fever ward which he considered overcrowded with cases of enteric fever and feared that progress would be hindered by efforts at the unattainable.—Dr. T. Glover Lyon said that though the cost of working his system was small, that of its installation was unavoidably considerable and often deterred hotel proprietors and others from adopting it. Owners and architects objected to the size of the fans and shafts, but while a six-foot fan making 500 revolutions per minute would be efficient and noiseless, one of two or three feet diameter revolving 1000 times would produce an intolerable noise with little effect save in its immediate proximity.—Dr. Kenwood doubted the expediency of forcing air into sewers, maintaining that their ventilation should be effected by powerful extraction only.—Dr. E. F. Willoughby, referring to Mr. Blyth's deprecation of all attempts at the ventilation of public buildings by other than fans, described the system adopted by Professor G. Fischer in the Memorial Church at Berlin where, by tiers of "heizkörper," or steam-coils, increasing in number to the summit of the dome, the foul air, instead of being chilled and sinking again, as in all similar edifices, passed out at the lantern in a continuous stream. Judging by the fact that at all seasons and under all circumstances a uniform temperature of 60° F. was maintained it would appear to be a complete success.

**DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.**—At a meeting of this society on Oct. 23rd, Dr. A. J. Harrison, the President, being in the chair, the following cases were shown. Dr. P. S. Abraham: (1) A case of General Progressive Scleroderma in a married woman, aged 49 years (in the discussion which followed Mr. Campbell Williams spoke of an allied case in a diver, Dr. Alfred Eddowes of cases of leukodermic alopecia, and Dr. J. H. Stowers of the case which he showed at the Dermatological Congress in 1881, in which the distal phalanges of the hands were entirely absorbed, the last speaker regarding the prognosis in these cases as being grave; Dr. Abraham, however, said that there were several cases of recovery on record); (2) Xanthoma Diabeticorum in a woman, aged 32 years (attention was called to the rareness of this condition in women and Dr. Wilfrid Warde gave a microscopical demonstration of the histology of the papules); (3) Lupus Erythematosus in a girl, aged nine years; and (4) Dermatitis Herpetiformis in a young girl (Dr. Wilfrid Warde suggested that this was a case of pemphigus foliaceus).—Dr. Stowers: A case of Paget's Disease of the Left Breast of 15 Years' Duration in a patient, 82 years of age. He called particular attention to the long duration of the disease without any glandular implication or scirrhous formation.—Dr. G. Norman Meachen: (1) A case of Lichen Planus Hypertrophicus in a Woman; and (2) a case of Lymphangioma Circumscriptum in the Left Axilla of a Woman (Mr. G. Pernet thought this to be a case of white

mole; there was a history of some, probably nævoid, growth having been removed from this region many years ago).—Dr. Graham Little: (1) Lichen Scrofulosorum in a Girl; and (2) Two Children with Parasitic Alopecia.—Dr. Eddowes: A case of Lupus Vulgaris.—Mr. Arthur Shillitoe: (1) Tertiary Syphilitic Indurative Oedema of the Scrotum, Lip, and Tongue; and (2) Secondary Syphilitic Tongue, showing Papillomata and Condylomata present at the same time.—The proceedings terminated with an address from the President on the Accident of Disease Dermatologically Considered.

**SOUTHPORT MEDICAL SOCIETY.**—The annual meeting of this society was held on Oct. 9th at the Temperance Institute, Dr. R. Harris being in the chair. The annual report and balance-sheet were duly adopted and the following officers were elected for the ensuing session:—President: Dr. C. Pinkerton. President-elect: Dr. F. J. Baildon. Vice-President: Dr. J. C. Russel. Committee: Mr. G. Reinhardt Anderson, Dr. P. Ashworth, Mr. A. H. Baines, Dr. W. H. Barrett, Dr. Harris, and Dr. G. C. Walker, sen. Honorary treasurer: Dr. Mewburn Brown. Honorary secretary: Mr. R. M. Littler.—Dr. Pinkerton then gave an inaugural address on Moveable Kidney. He dealt exhaustively with the causes, symptoms, complications, diagnosis, and treatment of this affection and laid special stress upon the frequency of obscure and intractable gastrointestinal symptoms. Numerous illustrative cases were quoted.

## Reviews and Notices of Books.

*A Text-book of Gynecology.* Edited by CHARLES A. L. REED, A.M., M.D. Illustrated by R. J. HOPKINS. With 355 Illustrations. London: Henry Kimpton. 1901. Pp. 950, 8vo. Price 25s. net.

THIS text-book of gynecology is the outcome of the coöperation of some 31 different writers. The method has been followed of obtaining contributions upon special subjects, such as pathology and dermatology, from various authorities who are not strictly gynecologists. As a result of the manner in which the book has been compiled a single chapter is in some instances based upon contributions from several writers, while the whole has been rendered consecutive, systematic, and homogeneous by the editor. This system has worked very well mainly owing to the care and supervision exercised by Dr. Reed. Here and there, as is inevitable in such a book, we find somewhat contradictory statements as, for example, in the chapter upon the Pelvic Floor and its Injuries with regard to the functions of the perineum, but such inconsistencies are few and far between. The general tendency of the work is surgical; this is well illustrated by the treatment recommended for uterine displacements, and by the section on the treatment of acute septic infections of the uterus in which we find curettage and hysterectomy alone advocated. The local medicinal treatment of the affections of the external genitalia, admirably described by Ravogli, is, however, fully considered. In the descriptions of mal-development of various portions of the genital tract the editor has availed himself of the services of Ballantyne, and the result is seen in several sections of much interest. Amongst other British contributors are Sinclair who writes upon Bacteria of the Uterus, Ovaries, and Fallopian Tubes, Mayo Robson who has contributed an article upon Recto-vaginal Fistula, and Murdoch Cameron who describes Cæsarean Section. In mentioning more particularly the work of these contributors we must not be thought unmindful of the very valuable portions of the book written by the remainder of the collaborators, representing, as they do, the best American teaching of the present day. General Pathology has been placed in the hands of Herzog and the result is a series of descriptions of much greater value than are usually to be found in text-books of gynæ-

cology. Where there is so much that is good it is difficult to select particular chapters, but we may call attention more especially to the description of Tuberculosis of the different portions of the Genital Tract by Whitacre, to the chapters mainly written by the editor himself, and to those upon the Urinary Apparatus by Harris and that upon the Rectum by Gant, the latter containing a valuable section upon Examination of the Bowel by Martin. A very suggestive chapter upon Pelvic Diseases and Nervous Affections by Dercum concludes the volume. We cannot agree with Dr. Reed when he states that Byrne is wrong in calling his operation of electro-hysterectomy a high amputation of the cervix. An almost precisely similar operation was performed with the scissors or knife by many of the adherents of supra-vaginal amputation of the cervix before the days of the electric cauter, and if the editor refers to Sir John Williams's book on "Cancer of the Uterus" he will see that it was his custom in performing this operation to remove almost the whole, and in many cases the whole, of the mucous membrane of the body of the uterus, without, however, including so much of the muscular tissue as Byrne does. This operation of electro-hysterectomy is undoubtedly a development of the operation of high amputation of the cervix, and the brilliant results obtained by its originator go far to confirm the views of those who still think that supra-vaginal amputation of the cervix, if properly performed, is likely to give good results in selected cases.

The chapters upon the Affections of the Fallopian Tubes, to which Clark and Coe have contributed as well as some of the writers already alluded to, are particularly good and worthy of perusal. Neoplasms of the ovaries receive full treatment by Rothrock, but in the chapter upon Ectopic Gestation there are several notable omissions. The illustrations are good and well reproduced. The editor has adopted the uncommon plan of describing them by quotations from the text. This answers well in some cases, but in others the description has little or no bearing upon the illustration, and does not in the least help to explain it or to call attention to the particular point it is intended to represent. There are some evidences of haste, and the references, almost uniformly incomplete, might well have been omitted. A full index is provided. On the whole the book is good and up to date and may be recommended to those who have already some knowledge of the subject.

*A Manual of Surgery for Students and Practitioners.* By WILLIAM ROSE, M.B., B.S. Lond., F.R.C.S. Eng., Professor of Clinical Surgery in King's College, London, and Senior Surgeon to King's College Hospital; and ALBERT CARLESS, M.S. Lond., F.R.C.S. Eng., Surgeon to King's College Hospital, and Teacher of Operative Surgery in King's College, London. Fourth Edition. London: Baillière, Tindall, and Cox. 1901. 8vo, pp. 1182. 406 Illustrations. Price 21s.

WHEN four editions of a book are published within a space of under two years it is obvious that there is a demand for such a book, and we can do but little here except congratulate Mr. Rose and Mr. Carless upon the success of their work. In reviewing the second edition we expressed a hope that the book would not be allowed to get any larger. That edition consisted of 1190 pages, while this, the fourth, consists of 1182 pages. The authors state in their preface that the present edition is practically a reprint of the preceding one, and scarcely a year has elapsed since the third edition appeared. We consider this work to be eminently suitable as a student's text-book because in the main the descriptions are clear and yet concise, so that practically all that a student need know of the vast science of surgery is contained within 1200 pages. It is difficult to see where the work could have been made briefer without a sacrifice of efficiency. The excellent skiagrams of fractures and dislocations should prove of great value to the reader,

but we would suggest that some of the diagrams might with benefit be replaced by more artistic productions. We may instance Fig. 180, which is quite unworthy of such an excellent text-book as the one before us.

*Encyclopædia Medica.* Under the general editorship of CHALMERS WATSON, M.B., M.R.C.P. Edin. Vol. VII. Edinburgh: William Green and Sons. 1901. Pp. 506. Price 20s.

THIS volume carries on the work from an article under the heading "Liver" to one under that of "Menopause." Many contributions of considerable interest and value will be found. The physiology and general medical affections of the liver were considered in the previous volume; in the section now before us we find a description of those conditions generally known as "tropical" and of parasitic affections of the liver. The author is Mr. James Cantlie. His remarks on hepatic abscess are particularly worthy of note. In common with most authorities on tropical diseases he considers that there is but little evidence to justify the belief that malarial poisoning has any direct influence in causing abscess of the liver. Although in many instances the two factors co-exist, yet they are by no means coterminous in their geographical distribution; moreover, the changes induced by malaria in the viscera generally are more in the nature of a cirrhotic or plastic nature than of a destructive or retrograde character. Mr. Cantlie further is of opinion that malaria serves merely to weaken the functional powers of the liver and thereby to render it more susceptible to disease and less fit to resist the influences brought about by chill.

Dr. J. F. Sutherland, deputy commissioner in lunacy for Scotland, writes an interesting article on Lunacy, dealing mainly with the legal aspect of the subject. This contribution should be a valuable one for reference, as it contains in a small space all the necessary information as regards the legal status of a medical man who undertakes the charge of insane patients.

Diseases of the lungs are considered in the following sections—Pulmonary Tuberculosis, Fibrosis, and Pneumokoniosis, by Dr. R. W. Philip; Gangrene of the Lungs and Emphysema, by Dr. S. H. Habershon; and Vascular Disorders, Syphilis, Abscess, and Parasitic Affections of the Lungs, by Dr. R. A. Fleming. All these articles are worthy of high praise and their authors have evidently spared no pains to render them as complete and up to date as possible. Dr. Philip's remarks on prognosis are interesting. He rightly lays stress on the caution which should be exercised in judging of the progress of the disease by the gain in weight. We think this caution most necessary. It is a matter of frequent occurrence that patients under the "hygienic" or "open-air" treatment gain weight considerably, whilst the temperature curve and physical signs show but little alteration. The patients are likely to lay too much importance on the gain in weight and therefore to wish to leave the institution sooner than is advisable. A gain in weight is certainly encouraging but is apt to be fallacious.

The article on Malaria is an excellent one and is by Mr. D. C. Rees. The section Parasitology, which describes the human and mosquito cycles of the malarial parasite, is particularly worthy of note and gives a good summary of the present knowledge on the subject.

There is an excellent article on Malingering, written by Mr. T. D. Patmore, late medical officer, His Majesty's prison, Wormwood Scrubs. In having to distinguish between true disease, hysterical phenomena, and symptoms purposely feigned for some ulterior object the practitioner is not unfrequently placed in a position of great responsibility and the greatest care and tact are required in examining a case and arriving at a conclusion. This difficulty has been added to in recent years by the custom of cloaking under

the term "neurasthenia" many cases of voluntary imposture, and whilst the vagaries and erratic action which an exhausted, or concussed, or shocked nervous system may indulge in must be appreciated, yet we agree with Mr. Patmore that it is to be noted with regret that there is a tendency to confuse nervous with voluntary phenomena. Mr. Patmore in his experience at Wormwood Scrubs prison was frequently brought into contact with malingerers, and his remarks, therefore, will carry considerable weight and make his contribution a valuable one.

Mr. H. J. Stiles is responsible for the section on Diseases of the Mammary Gland. He has made a very complete study of his subject, the section on Neoplasms of the Mamma being particularly well arranged. Amongst the other contributors to this volume are Dr. H. Harvey Littlejohn who writes on Forensic Medicine, and gives a good epitome of the principles of that branch of medical science; Dr. G. F. Still who writes on Tuberculous Meningitis and Posterior Basic Meningitis; Dr. W. Osler whose article on Epidemic Cerebro-spinal Meningitis is particularly worthy of note; and Mrs. Garrett Anderson who contributes a short article on the Menopause.

#### JOURNALS AND MAGAZINES.

*The Practitioner.*—This journal is still engaged upon its Fracture Numbers, the October issue being the third of the series. Considering the importance of the subject of fractures to medical men generally, the wide space allotted need not be grudged. Few cases are so injurious to a medical reputation as those of a fracture with permanent, perhaps avoidable, deformity. Moreover, for a comparatively simple and obvious disorder, and one which has had close attention for centuries, fractures have assumed a new aspect and have received novel and entirely different methods of treatment within quite recent years beyond almost any other large class of surgical cases. Mr. H. L. Barnard contributes an exhaustive communication upon Fractures of the Lower Extremity. Separation of the lower epiphysis of the femur is especially dealt with and some most interesting examples are given of boys who have entangled their limbs in a cart-wheel while hanging on behind. *Apropos* of fractured patellæ Mr. Barnard digresses into the question of irrigating the knee-joint and shows how commonly the posterior pouches of the synovial membrane are neglected, separate incisions being necessary if these are to be thoroughly drained. Two striking reproductions of skiagraphs represent respectively fracture of all the metatarsal bones and separation of the heads of the five outer metatarsals. Mr. F. C. Wallis illustrates his remarks on the Treatment of Paralysis and Muscular Atrophy after prolonged use of Splints or of an Esmarch's Cord by an unusual case of double congenital absence of the superior radio-ulnar articulations. Elaborate operative and electrical treatment secured a very gratifying result. A paper on Gastric Flatulence by Lydia Leney contains the statement, as the result of about 30 observations, that the volatile acidity of the contents of the stomach varies inversely as the presence of free hydrochloric acid. The editorial paragraphs touch upon the question of the reorganisation of the Royal Army Medical Corps and upon medical bulletins, *apropos* of which Sir Henry Hallford's opinion is quoted. Mr. James Berry's excellent work on the Thyroid Gland is reviewed at length and the "Causerie" deals with the late Dr. McNeill Whistler.

*The Journal of Hygiene.* Vol. I., No. 4. October, 1901. Cambridge: University Press. Pp. 99. Price 5s. net.—Malaria forms the subject of two papers in the current quarterly number. Captain Leonard Rogers, I.M.S., discusses in interesting fashion the Seasonal Prevalence of Anopheles and Malaria in Lower Bengal and the

practical application of the mosquito theory; whilst Dr. Nuttall and Mr. Arthur Shipley continue their studies in relation to malaria, the structure and biology of anophelids being here dealt with in considerable detail. There are, too, some excellent plates, one of which shows the anophelid *maculipennis* in the act of sucking blood. Captain Rogers finds that the conditions which obtain in Lower Bengal, whether in the rural districts or the small towns, are such as to render the destruction of the larvæ impracticable. The houses are largely constructed on raised earth platforms which are formed by the excavation of earth from the adjoining low-lying soil and the tanks thus produced can neither be drained nor treated with culicides. These tanks, Captain Rogers finds, form a most important breeding-ground for anophelids. The larvæ are, according to these observations, most prevalent in hot weather, while during the rains they diminish in number. Captain Rogers does not find that the presence of fish is fatal to the existence of the larvæ. Although he does not regard it as practicable entirely to destroy the larvæ he thinks that much may be done in the neighbourhood of towns by filling up the pools, by lining the surface-drains, and by abolishing rice-fields. There is much interesting matter in this paper. Dr. J. S. Fulton gives an account of a Milk-borne Outburst of Enteric Fever in America, while Dr. R. H. Makgill and Dr. W. G. Savage contribute papers on the Value of the Neutral-red Reaction in the Bacteriological Examination of Water. The number concludes with some further observations by Dr. Louis Cobbett on the recent Outbreak of Diphtheria in Cambridge, which was dealt with on commendably modern lines. Dr. Cobbett discusses the very difficult question as to the possibility of isolating persons who are harbouring in their throats the bacillus of diphtheria but who present no other indications of that disease. He concludes (and we incline to the same view) that it would be extremely inexpedient to press the isolation of such cases—inexpedient in the best interests of public health. To invite opposition is obviously undesirable, more especially when it can clearly not be said that a person in whose throat the bacillus is found is suffering from the disease diphtheria. Probably the application of an antiseptic throat-wash would be found a more practicable measure than enforced isolation.

## Analytical Records

FROM

### THE LANCET LABORATORY.

#### CONDENSED EGG.

(THE CONDENSED EGG SYNDICATE, LIMITED, 19, GUILTON ROAD, HACKNEY, LONDON, N.E.)

THERE is no mystery about these preparations; they consist simply of fresh eggs and refined sugar. In appearance the preparations are not unlike malt extracts—slightly opalescent and syrupy. We examined and submitted to analysis three preparations, the first containing the egg-albumen, the second the egg-yolk, and the third the entire egg. The egg-albumen preparation gave on analysis the following results: moisture, 31.65 per cent.; mineral matter, 0.81 per cent.; proteids, 10.87 per cent.; fat, 0.30 per cent.; and sugar, 56.37 per cent. The egg-yolk preparation gave the following results: moisture, 24.80 per cent.; mineral matter, 1.24 per cent.; proteids, 11.68 per cent.; fat, 22.00 per cent.; and sugar, 40.28 per cent. Lastly, the entire egg preparation gave the following results: moisture, 28.70 per cent.; mineral matter, 0.92 per cent.; proteids, 11.75 per cent.; fat, 9.20 per cent.; and sugar, 49.43 per cent. These results are in perfect accordance with the descriptions of the respective preparations. Thus the egg-albumen preparation contains the most moisture but only a trace of fat.

The egg-yolk preparation contains the least amount of moisture but a very large proportion of fat. The composition of the entire egg preparation comes between these two, as might be expected. The proteids, of course, represent the unaltered albumen of the egg coagulable by heating. We could trace no objectionable preservative. We have here undoubtedly a satisfactory method of preserving eggs, although for some purposes the presence of 50 per cent. of sugar is not desirable. The preparations answer well for cooking purposes, as in the making of custards or puddings or cakes. Necessarily the preparations are powerful foods, each tablespoonful representing the nutritive value of one egg. The preparations bore no sign of staleness or deterioration. Apart from their value for ordinary cooking purposes, it is no small achievement to be able to preserve so satisfactorily a preparation containing over 10 per cent. of soluble albumen.

#### OLD PEDIGREE PORT.

(MESSRS. MARTELL AND CO., GREAT TOWER-STREET, E.C.)

Pedigree port is described as a pure and reliable Spanish port grown in the choicest district, and made after the best Douro methods. We are quite certain that it is much more honest than many alcoholic liquids denominated as port. It is of a rich red colour and possesses a taste somewhat rough on the palate, but full and fruity. It cannot lay claim to elegance exactly, and we do not expect it at 1s. 6d. a bottle. For all that it is a sound and genuine wine and well adapted for the use of invalids whose means are limited. On analysis the following results were gained: extractives, 6.88 per cent.; sugar, 6.40 per cent.; mineral matter, 0.20 per cent.; alcohol, by weight 14.00 per cent., by volume 17.26 per cent., equal to proof spirit 30.26 per cent.; volatile acidity reckoned as acetic acid, 0.087 per cent.; and fixed acidity reckoned as tartaric acid, 0.356 per cent. The wine is somewhat acid. As regards alcoholic strength it is below the average for port wine.

#### IMPERIAL STOUT.

(BENSKIN'S WATFORD BREWERY, LIMITED, WATFORD.)

We have not examined a sample of stout with a greater proportion of malt extractives or nutritives than the one under notice. The results of analysis were as follow: malt extractives, 9.25 per cent.; mineral matter, 0.48 per cent.; and alcohol, by weight 7.73 per cent., by volume 9.62 per cent., equal to proof spirit 16.86 per cent. We could trace no objectionable preservatives. The stout is particularly well adapted for the requirements of invalids. It is of excellent malty flavour, highly nourishing, sound, and free from excess of carbonic acid gas. It is stated to be brewed from malt and hops only—that is, with no addition of sugar. It is free from sharpness of taste on account of its non-acid character. It is evidently a genuine malt liquor brewed from malt and hops only and of the best type. We understand that this stout has been used in the hospitals in South Africa, where very favourable opinions of it have been formed.

#### (1) BOROBENPHENE; AND (2) GLYCOPENPHENE.

(THE HENRY HEIL CHEMICAL CO., ST. LOUIS, MO., AND F. NEWBURY AND SONS, 27 AND 28, CHARTERHOUSE-SQUARE, LONDON, E.C.)

Borobenphene is a clear, colourless liquid containing, according to our analysis, glycerine, boric acid, benzoic acid, and phenol. It has a pleasant aromatic smell and, considering its ingredients, is, of course, strongly antiseptic. It is practically non-poisonous, the quantity of phenol in relation to the other antiseptics being small. Borobenphene, it is stated, does not coagulate albumen—a statement which we have been able to confirm by the fact that it is without a visible effect upon a solution of white of egg. The preparation is attractive and useful for domestic purposes. It may be used internally in, of course, restricted doses, and its taste is not unpleasant. In fact, it may agreeably be used in all cases where the application of an effectual antiseptic is desired. Glycopenphene has practically the

same composition, but differs in containing a considerable white deposit which proved on analysis to be zinc oxide. The preparation is said to give relief in eczema and to serve as an excellent dressing for wounds and sores.

#### DYMOL.

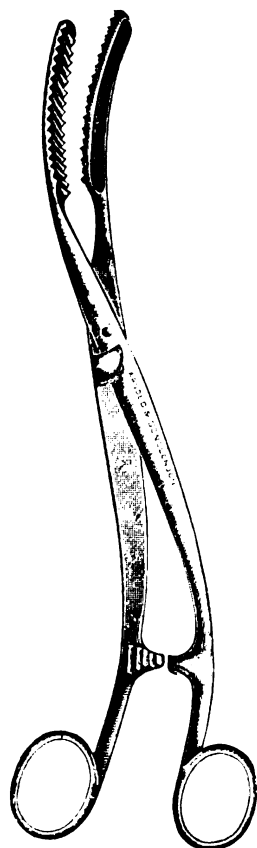

(LORD AND LORD, PHILADELPHIA; F. NEWBERRY AND SONS, 27 AND 28, CHARTERHOUSE-SQUARE, E.C.)

Dymol is an iodine compound insoluble in acid media, but decomposed in an alkaline environment. It contains nearly a third of its weight of iodine in organic combination. The iodine is readily obtained on treating dymol with a strong oxidising agent. It is a light brown powder without any irritating properties, neutral in character and insoluble in water and acid. It is described as an alterative and stimulating antiseptic for employment in gastro-intestinal disorders. It has thus been used in the treatment of diarrhoea, dysentery, cholera, and enteric fever. In other words, it produces intestinal antiseptics and is said completely to deodorise the stools. It is, practically speaking, non-toxic.

## New Inventions.

### SOFT CERVIX VOLSELLA FORCEPS.

THE accompanying illustration shows the new soft cervix volsella forceps which I devised and recently exhibited to the Obstetrical Society of London. The volsella catch, grip firmly, and pull down the soft dilated puerperal cervix without tearing or injuring the cervix or vagina, the fundus uteri being always pushed down by the left hand on the abdomen. The new instrument is specially made for the soft dilated cervix in abortions, premature or full-time labours, or soft dilated diseased cervix. This instrument is better suited in many ways for the above class of case than the sharp-pointed volsella or Teale's forceps, neither of these being specially made for the purpose. The blades of the new volsella are long and broad. The blade inserted into the os uteri has a slightly convex horizontally grooved and blunted serrated surface which fits accurately into the slightly concave corresponding surface of the other blade, thus obtaining a long, broad, and firm grip of the cervix without any laceration. The posterior surface of the closed instrument is smooth and polished, so that it slides along the back or side wall of the vagina easily. The anterior surface of the blade inside the cervix has a longitudinal groove along its whole length which can be used to guide the finger or curette into the uterus. The lock of the volsella is modern and the blades can be separated entirely and made aseptic. There is a clip at the handles which can be fastened at varying degrees of tightness. The handles curve towards the perineum so as to be out of the way of the operating finger or curette. The whole

instrument is very light and its weight if left hanging does not tear the cervix. The soft cervix forceps is made by Messrs. Arnold and Sons, West Smithfield, E.C.

Brook-street, W.

ROBERT WISE, M.D. Edin.

## THE ENTRIES AT THE MEDICAL SCHOOLS.

By the courtesy of the deans of the various medical schools we are enabled to give approximately the number of students who have entered upon medical study this year. There is some difficulty in obtaining figures made up to exactly the same period from the different schools, but the table of entries which follows is as complete as we have been able to make it :—

### ENTRIES FOR THE YEAR 1901-1902.

#### London.

Name of medical school.	Full medical course.	Special courses.	Dental.	Full course, 1900-1901.	Increase or decrease in full medical students over or under last year's figures.

\* Information not supplied.

† Including 68 Anatomy and Physiology, 36 Bacteriology, and 23 Public Health.

**WATER-SUPPLY OF NEWPORT.**—The Waterworks Committee of the Newport (Mon.) Borough Council made an inspection of the reservoirs of the town on Oct. 23rd. The lower reservoir was found to be practically empty, and in the upper reservoir there were about 50,000,000 gallons of water. It was decided to curtail the supply immediately. The water is now cut off from 11 P.M. until 5 A.M.

**WEST OF ENGLAND EYE INFIRMARY, EXETER.**—The annual meeting of the subscribers to this institution was held on Oct. 25th under the presidency of Mr. Smyth Osbourne. The secretary read the ninety-third annual report which alluded with satisfaction to the completion of the first two sections of the new building, they having been formally opened by Lady Clinton on Oct. 4th last. The financial statement showed that the ordinary income was £1435 and the ordinary expenditure £1442. The medical report stated that there had been 3010 patients under treatment during the past 12 months, of whom 2588 had been discharged, leaving on Sept. 30th last 389 out-patients and 33 in-patients under treatment. The daily average number of in-patients during the year had been 45. Mr. Hamlyn, high sheriff of Devon, was elected president for the ensuing year.

LONDON: SATURDAY, NOVEMBER 2, 1901.

## The Isolation Accommodation of the Metropolis.

THE increasing popularity of isolation hospitals and the difficulty which there is in meeting the demands which such popularity creates, form together one of the most serious problems of present-day municipal administration. As far as our experience and information go none of the big cities of the world is so well equipped in the matter of isolation accommodation as is London; and hence it may be of interest to examine the position of the metropolis at this moment in respect of its ability to accommodate its infectious sick. The expenditure upon such provision has been, and is, very material, but notwithstanding the fact that the Metropolitan Asylums Board has more than doubled its accommodation for fever cases since 1891, and that the proportion of scarlet fever admissions to notifications has risen from 42·82 to 75·15, we are still face to face with the fact that more accommodation is needed. In other words, the existing accommodation is not sufficient for the isolation of what may be called the ordinary infectious diseases, or, rather, such diseases as public health administration has, up to the present, deemed it desirable to provide accommodation for—i.e., scarlet fever, diphtheria, and enteric fever. Certainly provision is also at hand for the isolation of small-pox, but unfortunately it has been found difficult to keep unoccupied by other diseases all the beds originally intended for small-pox, and a threatened epidemic of this disease is found rather to dislocate the existing arrangements. More particularly is this the case when the murmurings of an exotic disease like bubonic plague tend to remind us that our boasted immunity from this disease may be imaginary rather than real, and when it is considered desirable to set aside a certain number of beds to isolate first cases of this malady. It is an unfortunate and unaccommodating dispensation of nature that the maximum prevalence of several diseases occurs at practically the same season or seasons of the year. Were there a degree of alternation in their prevalence administrative measures would be simplified. As nature works at present, there is an undue strain placed upon our hospital resources in the autumn and the winter months, and when small-pox tends to prevail there is likely to be a crowding-out of the less serious diseases.

Under these circumstances the Metropolitan Asylums Board has to adapt itself to the exigencies of the situation, and the distribution of its beds at the present juncture does not meet with the approval of the Town Council of the Royal Borough of Kensington, which body has addressed a communication to the Metropolitan Asylums Board on the subject. Briefly stated, the Kensington

Town Council deplores the temporary discontinuance of the admission of scarlet fever and diphtheria convalescents into Gore Farm Hospital at a time when these two diseases are unduly prevalent. This discontinuance has, we take it, been deemed necessary in order to provide, in one or another fashion, for the prevention or control of small-pox and bubonic plague. The Kensington Town Council, while admitting the necessity for the provision of beds for the isolation of small-pox, does not take such a pessimistic view of small-pox prospects as does the Asylums Board, and expresses the hope that the action of the metropolitan sanitary authorities will hold the disease in check. Curiously enough, the action or inaction of the guardians *quâ* vaccination receives no mention in the letter. We must confess that we are unable to share the optimism of the Kensington councillors even while we venture to hope that these views may prove to be correct. It appears to us that if small-pox in anything of the nature of an epidemic arises from the present smouldering embers London may be face to face with a serious emergency within the next few months, especially as the maximum seasonal prevalence of the disease has yet to come. Moreover, the returns of the last few days are not by any means encouraging. It is suggested that the Asylums Board would do well to provide hut accommodation for small-pox on the Joyce Green estate adjoining the hospital ships, but doubtless the managers have already considered, and are still considering, the practicability of this measure. It is conceivable that to provide adequate drainage on a site such as this for a large number of huts may be no simple affair and might interfere very materially with the permanent arrangements. Still, the managers will do well to keep this question to the front. But in the meantime ample accommodation should, in our opinion, be held in reserve for small-pox even if in the interval the accommodation for scarlet fever and diphtheria may have to be curtailed. When the isolation problem is viewed from a broad standpoint the admission has to be made that it is a very difficult matter to provide permanent accommodation which will suffice in the presence of epidemics of two diseases, to say nothing of the possible outbreak of a third. Assuming that such accommodation does not exist the most reasonable course is surely to select for isolation the more fatal class of the diseases in question, and if all cases of any one class cannot be isolated to make a selection of such cases as are most likely to be a danger to the public. Selective action in this sense may have in the future to be exercised more than it has been in the past.

The Asylums Board has now accommodation for over 5000 cases of infectious diseases other than small-pox, and when the projected measures are completed the provision in this sense will amount to nearly 6100 beds. For small-pox the existing accommodation, exclusive of huts on the Joyce Green estate, is some 1500 beds, and when the Joyce Green Hospital is erected 400 beds will be added to this number. This total provision for small-pox is, as Dr. ORME DUDFIELD, the medical officer of health of Kensington, points out in one of his recent reports, materially below the 2700 recommended by the Royal Commission in 1882. Whether the proposed accommodation will prove adequate or not is a subject upon which we would rather not

prophecy. It depends, we think, upon the degree in which primary vaccination and *revaccination* are carried out and upon the *type* of small-pox which we may have to encounter. With neglected vaccination or neglected revaccination and small-pox of a high degree of infectivity all the factors will be present which will enable small-pox to laugh at the recommendations of the Royal Commission. In the absence of the epidemic type of small-pox a smaller number of beds will suffice even with an indifferently vaccinated community.

### Puerperal Eclampsia.

AMONGST the most important of the problems in obstetric medicine that await solution is the causation of eclampsia and the best method of dealing with this disease when it occurs. These questions have recently been fully discussed both at the meeting of German gynaecologists at Giessen and before the Obstetrical Society of London.<sup>1</sup> It cannot be said that either of these discussions has done much to elucidate our knowledge of this condition. The theory that eclampsia is due to a toxic state of the mother's blood is the one that holds the field at the present day. We are, however, still ignorant of the nature of the toxin, ignorant of its source, and ignorant of the precise manner in which it produces its effects. If we follow the teaching of the French school of obstetricians we shall give our adherence to the view that the liver is the organ primarily at fault and that the essential condition is one of hepato-toxaemia, while if we accept the current German teaching we shall believe that the affection of the kidneys is the primary condition and that the other pathological changes met with in different organs play but a secondary part; they are, indeed, to be regarded as the result of the action of the poisons, and not as the cause of their presence in the body. The occurrence of convulsions during labour is a complication of so alarming a character and of so grave a nature that there is a danger of our bestowing too much attention upon the fits themselves and too little upon the very important pre-eclamptic condition—viz., the condition of the patient preceding the onset of the convulsions. The existence of the toxæmia of pregnancy, upon which so much stress is laid by many writers as the *fons et origo* of the majority of the disorders of pregnancy, is hardly as yet placed upon a firm scientific basis. Even if we admit that such a toxæmia does exist there are many blanks in our knowledge of the relationship between it and some of the diseases which it is supposed to produce. We are at the present day in considerable danger of basing our treatment of eclampsia upon a theory which further investigations may show to be far from the truth. The toxic theory no doubt furnishes a good working hypothesis, but in using it we must ever bear in mind the slender foundations upon which it rests.

The discussion at Giessen is chiefly remarkable for the large amount of experimental work that was brought forward, some of it of considerable value. It is mainly by the accumulation of such work carried out in the laboratory that our knowledge of this disease is likely to be increased. The paper read before the Obstetrical Society of London was concerned with the treatment of eclampsia

by saline transfusion. In the discussion that followed many of the speakers expressed some doubt as to the advantages likely to be derived from this mode of treatment. It was pointed out that on their first introduction both morphia and chloral were lauded as infallible panaceas for this disease, and yet at the present time their true value is far from being fully established. In the same way this method of saline transfusion will no doubt have its day of fashion and at last take its proper place in the therapeutics of eclampsia. The treatment is based upon the toxic theory and if this theory be correct it is likely to give good results. There is considerable danger, however, of this mode of treatment being discredited if it be applied indiscriminately to all classes of cases.

We are inclined to think that if a correct knowledge of the causation of eclampsia is ever to be arrived at attention must be mainly directed to the pre-eclamptic stages of the disease. Further investigations must be devoted to careful observation of all departures from the normal in the health of the pregnant woman. Then, and then only, will it be possible to practise preventive medicine—the highest art of all—in the case of the pregnant woman and of the foetus in utero. The opportunities of a scientific study of the various problems connected with pregnancy are at the present day almost *nil*; the length of time such patients remain in lying-in hospitals before their confinement is too short for any prolonged observations to be made, and work of this nature is impossible in private practice. It is an encouraging sign to see that, mainly owing to the strenuous advocacy of Dr. J. W. BALLANTYNE and the generosity of Dr. FREELAND BARBOUR, a bed is to be endowed and set apart for the study of the diseases of pregnancy in the Royal Maternity Hospital of Edinburgh. We can imagine no more worthy object for philanthropy than the endowment of such beds in some of our large maternity hospitals where the diseases of pregnancy and of the unborn child could be investigated with all the advantages of modern science. It is by research in this direction that we are most likely to gain a true knowledge of the problems of eclampsia and of the best means of preventing this dangerous complication of pregnancy.

### The National Dental Hospital.

ON the occasion of the distribution of prizes at the National Dental Hospital and College on Oct. 24th, Dr. G. VIVIAN POORE, who distributed the prizes, observed that it could not have escaped the notice of those assembled that the subjects for which he had handed out rewards were numerous and varied, and that the student of dentistry was expected to have a knowledge not only of the science underlying his professional work but also a knowledge of the more mechanical parts. There was, perhaps, no profession in which science and practice were so intimately blended. There was sometimes an outcry against specialism in medicine, and, perhaps, in some departments of medicine specialism was a little overdone, but nobody could cavil at the whole science and art of dentistry as an unnecessary speciality. It was an absolutely necessary specialty and one which could be perfectly defended and justified. It was well

<sup>1</sup> THE LANCET, April 27th (p. 1207) and May 11th (p. 1336), 1901.

known that the physician was supposed to be an offshoot from, or development of, the priest, and in the same way the surgeon had had his origin with the more mechanical person, the barber, and it was not many centuries ago when the barber and the surgeon were one and indivisible. The barber was a gentleman who wielded a sharp instrument sometimes clumsily and then had to repair the damage, and it was from this that the surgeon had gradually emerged. The dental profession was evolved in the same way and it remained a handicraft down to comparatively recent times; it was only within the memory of some of the older members of the profession that the dentist began to make a stand and determined that his profession should be a real profession, and that it should be established like the other branches of medicine.

It was very curious, said Dr. POORE, to note how every profession had to wait for the advance of collateral professions and handicrafts before it could advance itself, and he instanced as an example the profession of the chemist. Chemistry could not have reached the high condition in which it was now but for the help of the glass-blower. After the advance of chemistry and metallurgy it was possible to advance in dentistry, and there was nothing that had caused the recent progress in dentistry more than the importation at the beginning of last century of india-rubber and the invention of vulcanite which had made so many dental operations possible. Of course it was said of dentistry, as it was said of almost everything else, that as a craft and a science it was old as the hills, and that in Egyptian mummy cases evidences had been found of artificial teeth, but Dr. POORE doubted if the dentures found in Egypt were quite as practically useful as those of the present day. He doubted whether if CLEOPATRA had artificial teeth she wore them much except on a Sunday or when she was going on the water to meet ANTONY, and he rather suspected that when she came home to a little supper with CHARMIAN she took them out. This view of the artificial teeth of the ancients is, we believe, generally held; the dentures were æsthetic, not practical, in their object. In the present day artificial teeth are not only for ornament but also for use, in particular, Dr. POORE pointed out, they robbed old age of one of its disabilities. It was said that with the advance of age all the senses declined with one exception, and that was the sense of taste. There was no doubt but that dentistry had added to the comfort of life; and the profession at large was under a great obligation to the dental branch of it because it was becoming recognised day by day that for general health sanitation of the mouth was all-important and that amongst the measures of preventive medicine, or rather the officers of preventive medicine, the dental profession was taking a first place.

The special branches of medicine have very often originated great advances which are of value to medicine as a whole, and perhaps this cannot be better illustrated than by the obligation of medicine and of surgery to the dental profession in the matter of anæsthetics. Dr. POORE laid stress upon this, pointing out that dentists had to deal largely with an operation which caused short, sharp pain, that to them the practicability of annulling that pain, which was only momentary, occurred, and that therapeutic measures were devised and carried out successfully very largely at their instigation. The dentists had to wait

until the chemist had provided them with anæsthetics but they first dared to use them. Dr. POORE concluded a highly interesting address by alluding to the life of the dentist. Dentistry, he said, while a most valuable side of medicine, was a harassing and trying side, and it was very important for its followers to have some pursuit to relieve the burden of their professional life, some pursuit, scientific or otherwise, which took them out of doors, which refreshed their minds and gave them health. In our experience dentists take good care to get the surcease from toil which Dr. POORE recommends for them. They seem to us to cycle, to golf, and to fish with enviable regularity.

## Annotations.

"Ne quid nimis."

### THE HEALTH OF THE KING.

WE have every ground for stating that the recent rumours concerning the health of His Majesty the King are entirely without truth or foundation. He is in good health and has undergone no operation whatever. Some of our readers may have seen statements in certain newspapers so detailed in character as almost to preclude their resting entirely upon journalistic imagination. We are glad to be able to assure them that they need give no credence whatever to the sinister but, happily, untrue stories the publication of which cannot be too strongly deprecated since they cause needless and poignant anxiety to the country at large.

### THE IMPROVEMENT OF THE HUMAN BREED.

A HUXLEY Memorial Lecture, established by the Anthropological Institute in 1900 in memory of the late Professor Huxley, is given annually at the opening of the institute's session in October on some subject illustrating the work of Huxley in connexion with anthropological science, especially in regard to the origin and development of mankind. This year's lecture was delivered by Mr. Francis Galton, formerly president of the institute, who took as his subject the Possible Improvement of the Human Breed under the Existing Conditions of Law and Sentiment. The aim of the lecturer was to give a scientific basis to the problem of race improvement. The lecture will appear in full in the next issue of the half-yearly journal of the Anthropological Institute to be published in January next.

### LORD ALVERSTONE AT ST. GEORGE'S HOSPITAL.

THE prize-giving at a metropolitan hospital is generally graced by the presence of some person eminent in science, literature, or art, who hands over the prizes to the fortunate recipients and is expected to deliver his soul upon some subject more or less connected with the art of medicine. The prize-giving at St. George's Hospital, held on Oct 28th, was honoured by the presence of the Lord Chief Justice of England, and the meeting was held in the board-room, being presided over by the Dean of the School, Dr. Isambard Owen. Lord Alverstone expressed his thanks for the honour done to him in asking him to be present and with becoming modesty mentioned that his chief claim to be chosen was that he had been an almoner of gifts for an object closely connected with the welfare of the medical profession. Nearly 20 years ago a distinguished friend of his, a graduate of Cambridge and an old Harrovian, had left at his death a sum of money to be given at the discretion of the speaker to found a scholarship either for science or medicine in the University of Cambridge or of London. Lord Alverstone continued that mindful of his own connexion with the University of Cambridge he had devoted the money to that corporation and had

founded the John Lucas Walker Studentship in Pathology. The Lord Chief Justice went on to speak of the enormous advances which had been made during the past century, not only in medicine and surgery, but also in the character and status of medical students. He continued by remarking that some 12 years ago in the course of his professional work he had been much struck by the want of intercommunication between the various hospitals both in the metropolis and of these with the great provincial hospitals. Matters, however, might have improved since then. We think that we can assure Lord Alverstone that matters have improved. Owing to the multiplication of medical societies, to the reports of the proceedings of these societies in the medical press, and to the greater facilities for travelling, any work done in any great hospital of the United Kingdom is known throughout that kingdom in a very short space of time. We are certain that if any discovery is made which apparently tends to the good of humanity its discoverer is the last man to keep it back for the benefit of his own school. There is one thing, however, which may have led Lord Alverstone to imply—as we gather from the report of his speech that he did imply—that the medical profession is wanting in “liberality of dispensation of knowledge,” and that is this: discoveries in the medical profession, whether new operations, new facts in pathology or bacteriology, new views of treatment, or new theories as to disease and its causes, must be carefully checked over and over again. Premature disclosure, as happened quite against his will in the case of Dr. Koch's tuberculin, can lead to nothing but disappointment. So it is that perhaps it appears to a layman that the discoverer of some advance in the field of medicine or surgery has been exploiting such discovery for himself. But those who are among the toilers in such fields know that the discovery is only kept back until the crop is fully ripe.

#### GUY'S WILL.

REFERRING to the notice to correspondents under the heading of “Looking Back” in this issue we have extracted the following interesting particulars connected with Thomas Guy's will from the “Dictionary of National Biography,” vol. xxiii., p. 391. “Having thus a vast fortune he decided to carry out a project long contemplated, of providing for the numerous patients who either could not be received in St. Thomas's Hospital or were discharged thence as incurable. He consequently, in 1721, took a lease from the St. Thomas's governors of a piece of ground opposite the hospital for 999 years, and having pulled down a number of small houses began the erection of a hospital on the site in 1722, intending to place it under the same administration. When the building was raised to the second story he changed his mind and decided to have a separate government. The building, which cost £18,793, was roofed in before the founder's death, which took place on Dec. 27th, 1724, in his eightieth year. He was buried with great pomp, after lying in state at the Mercer's Chapel. Guy's will went through three editions in 1725 and was reprinted by the governors of Guy's Hospital in 1732. It was signed on Sept. 4th, 1724, and bequeaths lands and tenements in Staffordshire, Warwickshire, and Derbyshire to grandchildren of his deceased sister, about £75,000 in 4 per cent. annuities, mostly in sums of £1000, to about 90 cousins in various degrees, as well as some persons apparently not relatives, and annuities varying from £10 to £200 per annum to others, mostly older relatives, being the interest on about £22,000 stock. £1000 was left to discharge poor debtors in London, Middlesex, or Surrey in sums not exceeding £5 each (600 persons were relieved by this benefaction, Maitland, p. 668). £400 per annum was left to Christ's Hospital for the board and education of four poor children annually, to be nominated by the

executors, the governors of Guy's, with preference to Guy's relations. His almshouse and library at Tamworth was left in trust for the maintenance of 14 poor persons of parishes surrounding Tamworth, excluding the town itself, preference being given to his own poor relations, a portion of the endowment being applied to apprenticing children, and nursing four, six, or eight persons of the families of Wood or Guy; while £1000 was left to other persons for charitable purposes. The remainder of his fortune, amounting to more than £200,000, was left to Sir Gregory Page, Bart., Charles Joye, treasurer of St. Thomas's Hospital, and several other of its governors, including Dr. Richard Mead (*q.v.*) to complete his hospital for 400 sick persons who might not be received into other hospitals from being deemed incurable, or only curable by long treatment; lunatics up to the number of 20 were to be received for similar reasons; but full discretion was given to the executors for varying the application of the funds. The executors and trustees were desired to secure an Act of Parliament incorporating them with other persons named, all governors of St. Thomas's, to the number of 50, with a president and treasurer; they were to purchase lands, ground rents, or estates with the residuary estate, and maintain the hospital by the proceeds, any surplus to be applied to the benefit of poor sick persons or for other charitable uses. The will was proved on 4th Jan., 1724-5. The required Act of Parliament was obtained in the same year (11 George I., cap. xii.), and gave power to the executors to set up a monument to Guy in the chapel, which was designed by John Bacon, R.A.”

#### “ARSENICAL POISONING FROM BEER-DRINKING IN ITS RELATION TO THE STUDY OF INEBRIETY.”

IN the Proceedings of the Society for the Study of Inebriety for September is published a paper with the above title by Dr. T. N. Kelynack. The writer draws attention to the recent outbreak of arsenical poisoning in beer-drinkers in the north of England and describes the clinical features of the cases which occurred; he also discusses the etiology of peripheral neuritis, upholding Schmiedeberg's teaching that alcohol is a true nerve and muscle poison; he insists, further, that its toxic action may be augmented and enforced by other agents. Dr. Kelynack then asks the question, What fresh light does the recent outbreak of arsenical poisoning in beer-drinkers throw on the pathology of inebriety? He argues that alcohol and arsenic act upon nerve tissue in many ways in a similar and in some respects in an identical manner, and that therefore it will probably be found that very real and definite cellular changes underlie what is usually termed inebriety. He supports this theory by quoting the works of Mott, Ford Robertson, and others in this country, and the researches especially of Lugaro and Marinesco among continental investigators, which have afforded evidence as to the true nature of many forms of mental disease, and Dr. Kelynack is of opinion that these observations when further pursued will bring inebriety into the group of morbid conditions dependent upon derangement of nerve-cell vitality. He also considers that in the future the influence of possible enforcing and accentuating agencies, such as arsenic, will have to be considered more fully. This drug, alcohol, and similar bodies have been proved to be capable of acting directly on the neuron. The degree of action depends upon the nature and intensity of the toxic agent, and doubtless also on many physico-chemical changes the nature of which has not yet been determined. We agree with the writer in his remarks on “considerations for the future.” Beer has undoubtedly been long contaminated with arsenic in some districts. The danger from contaminated malt and the extensive use of sugar substitutes in this country have

been amply demonstrated and we trust that history will not repeat itself. We support Dr. Kelynack in saying that scientific investigation should be undertaken by those intrusted with the care and management of inebriates in the various retreats and reformatories. The admirable work which is being carried on by pathologists in connexion with our public asylums, and especially in those under the control of the London County Council, warrants the belief that similar researches into the factors underlying inebriety would be fruitful in valuable results both to science and to humanity.

#### SMALL-POX IN LONDON.

SMALL-POX is increasing day by day. On Sunday, Oct. 27th, there were 21 fresh cases admitted to the hospital of the Metropolitan Asylums Board; on Monday, Oct. 28th, there were 25 fresh cases; on Tuesday, Oct. 29th, there were 28 fresh cases; and on Wednesday, Oct. 30th, there were 29 fresh cases. In view of the continuation of the epidemic it is stated that the staff of the General Post-Office have been strongly advised to be revaccinated without delay.

#### THE ELECTION OF DIRECT REPRESENTATIVES.

OUR advertisement columns contain formal notices that, pursuant to the Medical Act of 1886, elections are about to be held of two members to represent the registered medical practitioners of England on the General Medical Council and of one member to represent the registered medical practitioners of Scotland. The candidates as yet before the English constituency are Dr. J. G. Glover, Mr. George Brown, Dr. S. Woodcock, Mr. George Jackson, and Dr. C. W. Hayward: while there will be probably a contest in Scotland as Dr. C. E. Robertson has announced his intention of standing.

#### SPONTANEOUS RUPTURE OF THE ABDOMINAL WALL IN ASCITES.

SPONTANEOUS rupture of the abdominal wall in ascites is a very rare incident. Most of the published cases belong to a period when paracentesis was less practised than it is now. At the meeting of the Société Médicale des Hôpitaux of Paris on July 19th M. Pierre Merklen and M. Gougelet related the following case. A woman, aged 68 years, had ascites for nearly two years, probably from alcoholic cirrhosis of the liver. The heart was weak and there was œdema of the lower limbs. From May, 1899, to February, 1901, paracentesis was performed 25 times, and from 14 to 16 litres of fluid were removed on each occasion. The patient had an old umbilical hernia. The abdominal distension caused the opening to enlarge until several fingers could be passed into it and the hernia became as big as a large orange. It diminished after paracentesis, but in spite of methodical compression enlarged again. The umbilicus gradually became thinner, and in December, 1900, a little blackish scab appeared on its summit. This disappeared after paracentesis, but then recurred. On March 15th, 1901, 17 days after the twenty-fifth paracentesis (the interval between the paracenteses being usually 25 or 26 days) the scab fell off, disclosing a fistula of the breadth of the meatus urinarius and with suppurating walls. The ascitic fluid at once began to flow. The patient, seated on a chair, voided it in about two hours. On the following day there was continual oozing with disappearance of the abdominal swelling and the œdema of the legs. But the day after rupture there were abdominal pains and fever, and the next day intractable vomiting and dry tongue. Death from peritonitis occurred on the seventh day after rupture. In the recorded cases of rupture of the abdominal wall in cases of ascites paracentesis is not mentioned. The umbilicus was most frequently the seat of rupture and often, but not invariably, an umbilical hernia prepared

the way for distension and sloughing of the umbilical cicatrix. In cases of ascites complicated by a communicating hydrocele rupture has taken place in the scrotum. Rupture is most likely to occur where the skin is thinnest. However, it has occurred in the abdominal wall between the pubes and umbilicus—after phlegmonous gangrene. In the other cases rupture was preceded by greater or lesser sloughing of the skin and suppuration; hence the danger of peritonitis. Death is the usual result of rupture at the umbilicus, but recovery is not impossible and old writers thought this "puncture made by nature" a fortunate incident. Rupture of the abdominal wall in cases of ascites should be prevented. The only treatment when sloughing is threatened is frequent paracentesis.

#### THE VENTILATION OF THE "TWO PENNY TUBE."

THERE is no doubt that the measures adopted on the Central London Railway for the ventilation of the "tube" are, in face of the enormous number of people daily travelling on the line, inadequate. We pointed out some time ago that it is well known that the air of the "tube" has not grown pleasanter as the popularity of the system has increased. Even on passing the booking-offices of the stations or the lift exits an unpleasant sickly whiff is experienced. Our remarks are now fully borne out by the results of a series of interesting experiments made by Mr. A. Wynter Blyth, the medical officer of health of St. Marylebone, and his son. Details of these experiments will be found in the presidential address which we publish in our present issue delivered by the former at the annual meeting of the Incorporated Society of Medical Officers of Health on Oct. 25th. It is found that the carbonic acid gas at some stations was no less than 10·3 parts per 10,000, while between the stations—that is to say, in the tunnels—it reached 11·9. Now, since the average amount of carbonic acid gas in the outer air seldom exceeds 4 parts per 10,000 and that whenever the amount of carbonic acid gas in the air of a room exceeds this amount by two parts per 10,000 it is not fresh and has a stuffy smell, six parts per 10,000 has been fixed as the limit of impurity. The "tube" air contains nearly twice this amount. We remarked long ago that it is nonsense to say that the mere passage of the trains through a tight-fitting tunnel is sufficient to ensure satisfactory ventilation. Mr. Wynter Blyth's experiments clearly show that where the ventilation depends entirely on the passage of the trains, although there is so much movement of air, and so much sucking in from above and blowing out from below, a good portion of the air must be driven backwards and forwards unchanged in the tube; in other words, the tunnel air is diluted, but the whole of it is never swept out. This has all along been our contention. The amount of carbonic acid gas in the tunnels—and, be it remembered, this is very largely, if not entirely, of human origin—is more than double that of the outside air. It would be interesting to know what a bacteriological examination would reveal. As time goes on, unless additional and more effective ventilation by fans is adopted, the condition of the tunnel will go from bad to worse. These observations might usefully have been extended to the air of the cars; the results would probably have shown a greater pollution still. It is remarked that even as it is, the air of the Metropolitan Railway, as regards carbonic acid, is more than twice as bad. We are not sure that this is correct. for in the methods usually adopted for estimating carbonic acid gas the sulphurous gases are included. We are inclined to doubt whether the carbonic acid from human sources is any more on the Underground Railway than in the tunnel of the "Two penny Tube." The chief impurities in the former case are derived from coal. It is, further, evident that others

share our view as to the unpleasant character of the air on the Central London Railway, for we understand that an experiment with a system of ozonisation is going to be made shortly by a syndicate.

#### THE LATE PRESIDENT OF THE UNITED STATES.

THE medical staff attending the late President William McKinley, whose lamented death occurred on Sept. 14th, have issued a very detailed clinical and pathological history of the symptoms and the effects of the bullet-wound. This report, which would occupy about 16 to 18 columns of THE LANCET, will be found in *American Medicine* of Oct. 19th and is signed by the following gentlemen: P. M. Rixey, Matthew D. Mann, Herman Mynter, Roswell Park, Eugene Wasdin, Charles McBurney, and Charles G. Stockton.

#### THE INFLUENCE OF CLIMATE UPON FUNCTIONAL NERVOUS DISORDERS.

PROFESSOR F. S. PEARCE, neurologist to the Philadelphia Hospital, in the *New York Medical Journal* of Oct. 5th deals with the interesting and practical subject of climatic influence in regard to functional nervous and mental disorders. The effect of decreased atmospheric pressure in permitting a freer circulation in the surface of the body is an important fact in aiding circulation, just as massage applied to the body also increases the circulation of blood owing to the *vis a tergo* produced by the masseur. It is also possible that, as pointed out by Jaquet,<sup>1</sup> the action of high altitudes is not only a diminution of pressure but a chemical modification of the blood, in that more nitrogen is admitted into the blood under conditions of lowered atmospheric pressure. So that probably there is a double mode of action—viz., an increase of the peripheral circulation and an increase of the nitrogenous element in the general circulation. To these must probably be added the purity of the air and the more intense sunlight of high altitudes, both of which, according to Dr. Pearce, act as stimulators of bodily metabolism. The effect of winds is reflex, the strong stimulation of the skin and peripheral nerves causing increased excitability of the general bodily functions. The results, however, are not uniformly beneficial in all subjects. Hence in neurasthenia, where a weakness and irritability of the nervous system are the dominant conditions, high winds are to be avoided and altitudes above 2000 feet should also be eschewed, because they tend to hasten metabolic processes too rapidly and therefore cause physiological overwork of the central nervous system. This is also shown by the palpitation of the heart occurring in normal (or nervous) people at high altitudes. Similarly hysterical subjects are found to do badly at high altitudes for the same reason of increased excitability caused by over-activity in the peripheral circulation, and insomnia in them is more pronounced at heights, due perhaps to the increased circulation in the membranes of the brain. Climates with continual fogs and a low atmospheric pressure are also bad for the neurasthenic and the hysterical and the tendency to "catch cold" is aggravated in a moist atmosphere. Melancholia, on the other hand, needs increase of circulation and of metabolism, and subjects of melancholia usually improve by going to the mountains, where reduced atmospheric pressure, purer air, and more intense sunlight are obtainable than in the lowlands—a trio of meteorological conditions with a powerful adjuvant effect. High winds will be stimulating to the melancholic or to the hypochondriac and will tend to benefit him. Chorea is a disease made worse by high winds and increase of altitude beyond the happy mean of a few hundred

feet. As regards insomnia Dr. Pearce looks upon a condition of cerebral vaso-dilatation as being the main factor, so that whatever will tend to depletion or vaso-constriction of the brain will tend to allay insomnia. Thus it is that warm baths and massage before bed-time help to secure sleep. If these measures and drugs fail nothing is better than a quiet sea-voyage.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Oct. 24th states that for the week ending Oct. 19th the cases of plague in the Cape Peninsula numbered 1, that of a European. At Port Elizabeth the cases numbered 1, also that of a European. For all other places the cases numbered 1, that of a Chinaman. The deaths from plague were as follows: Cape Peninsula, 1, a European; Port Elizabeth, 1, a Chinaman; all other places, 1, a Chinaman. The area of infection remains unchanged with the exception of 1 case of plague, that of a Chinaman discovered at Uitenhage. The cases of plague among persons under naval and military control number 1, that of a private in the 1st Battalion Royal Scots employed as cook at Greenpoint Camp, Cape Town. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Oct. 25th states that for the week ending Oct. 24th there were 71 cases of plague and 37 deaths. With regard to Egypt the Director-General of the Sanitary Department writing from Cairo Oct. 20th states that during the week ending Oct. 20th 3 cases of plague and 2 deaths from the disease have been reported from all Egypt. Alexandria has reported 1 case and 1 death. Mit-Ghamr 1 case and Zeftah 1 case and 1 death. All cases and deaths during the last week have occurred among Europeans of Greek nationality.

#### POSTPONEMENT OF THE SECOND INTERNATIONAL CONGRESS OF THE MEDICAL PRESS.

AN official circular has reached us announcing the postponement of the Second International Congress of the Medical Press. The first congress, it will be remembered, was held in Paris from July 26th to the 28th, 1900. It was then agreed that national associations of the medical press should be formed in the various countries represented. The Paris committee which had organised the first congress was to prepare a scheme or a set of rules for the formation of an international association of the medical press. The draft of this project was to be sent to each national association, by which it was to be discussed and, if necessary, amended. Then the delegates of each national association were to meet this year in Brussels, to submit their amendments to each other, and jointly to draw up a definite scheme. The meeting of these delegates was to be held a day or two before the assemblage of the Second International Congress and the congress was to confirm or to amend the work of the delegation. The plan, it will be seen, was thorough in all its details, and it was fully explained in THE LANCET of April 27th last (p. 1237). But it is easier to frame a constitution on paper than it is to carry it out in practice. As we foresaw, the position and character of the various medical journals are so very different that it is no easy matter to bring them together. Then there is the fundamental difficulty of defining what constitutes a medical journalist. The Brussels committee appointed to organise the Second International Congress of the Medical Press now explains in its circular that it has not yet been able to accomplish its task. There has been an enormous amount of correspondence and this has rendered manifest the disagreement that

<sup>1</sup> Archives des Sciences Physiques et Naturelles, December, 1900.

prevails as to the nature of the questions that should be submitted to the congress. The principle of forming an international association of the medical press is enthusiastically approved, but there is a great diversity of opinion as to how this association should be composed. To hold another congress before a better understanding can be arrived at would only result in eloquent but probably futile discussions. Therefore, the Brussels Committee of Organisation proposes that the second congress should be postponed till next year. It further proposes that the central committee nominated at Paris last year should utilise the meeting of this year for the constitution of a universal committee and the elaboration of the statutes of the international association. There is every reason to believe that this project will be accepted. In that case the Paris Central Committee will call upon the medical press of each section to designate representatives to attend this proposed preparatory meeting. The circular concludes by requesting the medical journals to which it is addressed to approve this plan of action. Communications to that effect, or making any other suggestions, should be addressed to the secretary, Dr. V. Pechère, 140, rue de la Loi, Brussels. Under these circumstances it seems to us that the best course is to endorse the action of the Brussels committee. It is certainly no use to hold a congress unless there is a fair prospect of arriving at a general and practical agreement.

#### BLOOD-PRESSURE AND CHLOROFORM.

IN the course of some very instructive experiments on the effect of chloroform upon the blood-pressure in the lower animals Dr. R. D. Rudolf of Toronto records the following observations. He was struck by a curious fall of pressure which occurred more than once when dogs were under the influence of morphine and chloroform. In these cases the latter drug had been discontinued for several minutes before the fall occurred, and although no steps to restore the pressure were taken—indeed, while the conditions of experiment remained unchanged except by the lapse of time—the pressure rose to its original level. The tracings given suggest vagal irritation, a possibility Dr. Rudolf discusses, but no reason for the irritation was present, and as the pressure recovered itself under unchanged conditions it is hard to understand how such a factor was really at work. With regard to the effect of gravity upon the circulation, this observer's experiments confirm those of Leonard Hill and Barnard. Thus a chloroform-morphined animal will, upon raising its head and body, show a marked fall of carotid pressure; when it is placed horizontally the blood-pressure becomes over-compensated but soon returns to the normal. The compensation is held to be due partly to increased rate of heart-beat and to arterial constriction and partly to contraction of the abdominal walls. Dr. Rudolf found that "the lowering of a pole of the body does not raise the arterial blood-pressure in it so much as raising that pole lowers it." It is important to note that dogs vary very much in the extent to which blood-pressure is modified by the action of gravity under chloroform, and that cats especially are immune from such effects, while, as Leonard Hill has pointed out, some monkeys actually over-compensate, showing an increased blood-pressure when put into the feet-down posture. Generally, animals which habitually carry themselves vertically compensate more rapidly and better than those which normally assume a horizontal position. But such compensation sooner or later fails if the feet-down posture is maintained. Dr. Rudolf believes further—and his tracings appear to bear out his contention—that pressure exerted upon the abdomen is unable to restore carotid blood-pressure unless it is so firm as to compress the aorta. He regards as wholly inadequate the commonly accepted view that pressure acts by forcing

the blood out of the abdominal veins and so fills the heart. It has long been known that a tourniquet upon the abdominal aorta is one of the best means of raising general blood-pressure. Further, he finds that division of the spinal cord always produces a great lessening in the compensation for the feet-down position. Even when the vessels of the splanchnic area are not paralysed, the spinal section having been made well below the seat of the issue of these nerves, a very marked fall seems to follow the feet-down position, while no compensation occurs. "This would point," Dr. Rudolf says, "to the fact that the vessels of the lower part of the body are very largely concerned in the keeping up of the normal blood-pressure in the feet-down position, because when they are paralysed the pressure markedly falls." These conclusions—or perhaps it is more accurate to say these facts—are of great importance and are grouped by Dr. Rudolf as an introduction to his further researches.

#### MODE OF TERMINATION OF THE RENAL NERVES.

IN an article contributed to the nineteenth volume of the *Anatomischer Anzeiger* Dr. v. Smirnow gives the results of his investigations on the mode in which the renal nerves terminate. It was found that besides the nerves distributed to the walls of the vessels there were others which are in close relation to the tubuli uriniferi. These last form a plexus on the membrana propria of the tubules, and from the plexus varicose fibres proceed that terminate in dendritic or tree-like branches named "epilemmal nerve endings." Such endings are found both on the outer surface of the capsules of Bowman and upon the contorted tubes. Other branches of the plexus perforate the membrane and running between the cells of the tubuli and on their surface terminate in very different ways in the form of "hypolemmal nerve endings." They often present a grape-like aspect and resemble the nerve terminations that are found in the salivary glands.

#### THE CHEAP PISTOL AGAIN.

WRITING of the murder of President McKinley we dwell upon the unnecessary and avoidable danger to human life which is the result of the unrestricted sale of cheap pistols—toys which are useless for purposes of self-defence because they are untrustworthy, but which fired point-blank and favoured by chance become deadly weapons in the hand of the murderer or suicide. Two recent crimes committed in London and prominently reported in the newspapers have again illustrated the need for regulating or for suppressing by the imposition of duties or otherwise a trade which endangers the lives of peaceful citizens while conferring no compensating advantage upon anyone. In the case of what has been dubbed the "Blackfriars tragedy" two lives were lost. The murderer killed himself on the spot; his victim lingered for many days but has now succumbed; and her husband, it has been stated, might have shared her fate had not something hard in his pocket or his clothing obstructed a bullet from the gimcrack weapon which had already wrought such dire mischief. In the "Leicester-square tragedy" one victim, again the one who fired the shots, has succumbed, while the other appears to be on the road to recovery, although shot in the body not far from the heart at close range. Instructive evidence has been given at the inquest in this case as to the purchase of the weapon. It was bought in Houndsditch for 5s. 6d., and as there was evidence that the young foreigner who bought it was practically destitute we may infer that had the desired firearm cost pounds instead of shillings it would have been beyond his means, while the necessity for obtaining a ten-shilling gun licence before being allowed to possess it might have proved an insurmountable obstacle. In both of these cases murder and

suicide might, as we are aware, have been committed without firearms, but murder and suicide by poison, the bludgeon, the knife, or other possible agencies would have been far less easy, rapid, and certain. It is the cheap pistol which places the lives of ruler and subject alike in the hands of the criminal and the insane, whether those with murderous propensities be weak or strong, cunning or stupid, irresolute or determined, and the matter is one which deserves the attention of Parliament, to be bestowed irrespectively of party politics or of the complaints of individual constituents.

#### DIAGNOSIS OF SMALL-POX.

At a meeting of the Johns Hopkins Hospital Medical Society held on May 20th, 1901, and reported in the September number of the *Bulletin* Dr. Otley J. Porter of Columbia, Tennessee, described an epidemic that has recently prevailed in that section of Tennessee in which he lives. For a time the diagnosis was in dispute, some regarding it as chicken-pox, others as a new sort of eruption—"the bumps"—and a few recognising it as true small-pox. Meanwhile, in the uncertainty there was no efficient action or isolation and the disease spread until there were 1000 cases. Dr. Porter exhibited casts of the eruption and threw pictures on the screen showing that the disease differed in no way from the small-pox of the text-books, there being cases of hæmorrhagic, confluent, semi-confluent, and discrete small-pox as in other epidemics. The mortality also was the same, all the hæmorrhagic cases (five or six), 40 per cent. of the confluent, and from 10 to 15 per cent. of the discrete dying. In the 1000 cases there were some 15 cases of the disease in the fœtus in utero, several of which Dr. Porter had himself delivered. In the subsequent discussion Dr. Fulton said that it was not surprising that errors of diagnosis had been frequent in the history of the small-pox epidemic prevailing in the United States, for the disease might depart widely from the text-book description, though not more widely than typhoid fever did, and these variations were no less manifest in its epidemic characteristics than in the individual cases. The medical student of to-day had no chance to observe the disease, and had therefore no mental picture of the disease other than that gained from the text-books. Comparatively few practitioners under 50 years of age had seen the disease, while the older men remembered it by the more impressive characteristics of its appearance years ago.

#### "VOLCANIC ACTION AS A CAUSE OF OUTBREAKS OF EPIDEMIC DISEASE."

UNDER this heading Dr. Noel Bardswell of the Deeside Sanatorium at Banchory, Aberdeenshire, wrote an essay which gained the Parkin prize of the Royal College of Physicians of Edinburgh in 1900, and is published in the October number of the *Edinburgh Medical Journal*. In 1851 Dr. John Parkin, from whom this prize derives its name, brought out a large work on "The Remote Cause of Epidemic Diseases," in which he took the view that volcanic action was to be regarded as a factor in the causation of cholera and other epidemic diseases. Speaking generally the countries most liable to earthquakes are Portugal, Italy, Beloochistan, Afghanistan, the Bengal Presidency of India, Japan, Mexico, and the Pacific coast of South America. Dr. Bardswell is of opinion that the presence of volcanic activity in a country as a whole has no obvious effect on the death-rate or incidence of epidemic disease, but there is an evident difference in this respect between the volcanic and the non-volcanic portions of such countries. He applies this argument to selected portions of the United States of America and to selected portions of Italy, but, as he himself admits, the results obtained in this way must be received with caution. It seems to him, however, to be not unlikely

that volcanic action may have an effect on the mortality in towns possessing modern water-supply and drainage systems. Yokohama in Japan is situated in a district almost constantly under the influence of seismic disturbance and formerly had a very high death-rate from epidemic diseases, especially cholera and typhoid fever, but since the reservoirs and other water receptacles have been incased in puddle-clay and special precautions have been taken in the laying of the water-mains the health of the town has greatly improved. The methods adopted to guard against injury to the water service by earthquake shocks have been described by Mr. Turner in the *Transactions of the Institute of Civil Engineers*, vol. c. In 1887 a fairly severe shock of earthquake traversed the Riviera and did a great deal of damage. In addition to the destruction of houses, great cracks were made in cesspools and drainage-pipes were rendered leaky. In the three towns of Nice, Cannes, and Mentone the combined deaths from enteric fever were as follow:—41 in 1886, 66 in 1887, 115 in 1888 (the year after the earthquake), and 84 in 1889. The effect of earth tremors upon drainage and water-supply systems is, therefore, of much practical importance in certain localities.

#### BREAKING UP THE STREETS.

THE nuisance, the waste of time, the loss of temper, and the expense incident upon the fatuous way in which companies of various sorts—to say nothing of vestries or borough councils and the Post Office—break up the roads and footways have been well known to everyone for some time past. At last, however, there are signs that the hitherto patient worms, namely, ratepayers, are turning and the various articles and letters which have appeared in the public press are ominous of a gathering storm. Repairs and alterations are necessary, but what is absolutely unnecessary is the exasperating manner in which the blockage is made to be consecutive. We have a personal acquaintance with a certain street in South Kensington which recently for some 13 months was up in one portion or another. We have forgotten the exact order in which the various companies descended on their prey, but one after another came—electric lighting companies, hydraulic power companies, telephone companies both National and Imperial (i.e., the Post office) until the road and footways were impassable. Finally, the vestry relaid the paving of the footways. Scarcely was the mortar between the stones dry when they were all grubbed up again for the laying of pipes or wires. Undeterred by this the vestry next enclosed the whole roadway and with commendable promptitude relaid it with new wood blocks. Directly it was finished the owners of some new flats dug a trench from the middle of the roadway to the pavement for some connexions for electric light. The tradesmen in the street naturally complained bitterly, but no redress was obtainable. From a letter which appeared recently in a contemporary the same process is going on in Chester-square. And all over London the same idiotic want of organisation is apparent. A system of universal subways is perhaps utopian, and even were such a system possible gas, electric, and water mains could not be laid in the same tunnel for fear of explosion. But some relief from the present distress must be found. As we write, the Strand, which was relaid with new wood this year and which has only just recovered from a severe attack of electric-lighting company and Post Office, is a chaos opposite Agar-street owing to the operations of a water company.

THE Presidential Address of the Chelsea Clinical Society was delivered on Oct. 15th at the Jenner Institute by Dr. Charles Morris, C.V.O., the subject being "Some War Sequelæ." The address was an account of work done at home amongst sick and wounded officers from South

Africa and will be published in a later issue of THE LANCET.

DR. JUDSON S. BURY, physician to the Manchester Royal Infirmary, will give the Bradshaw Lecture before the Royal College of Physicians of London on Tuesday, Nov. 5th, at 5 P.M. The subject is "Prognosis in Relation to Disease of the Nervous System."

AN investiture was held at St. James's Palace on Oct. 29th when many gentlemen who have been awarded honours in connexion with the Army Medical Services in South Africa received their decorations at the hands of His Majesty.

## THE GENERAL MEDICAL COUNCIL: ELECTION OF DIRECT REPRESENTATIVES, 1901.

TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—At the urgent solicitation of medical brethren in whose judgment I have confidence I beg to offer myself as a candidate for election to the General Medical Council.

I have been in general practice in Manchester 35 years, during which period I have held appointments as Poor-law medical officer, public vaccinator, and certifying surgeon to factories. I am a member of the Central Council and chairman of the Parliamentary Bills Committee of the British Medical Association and I am also a member of the Reconstitution Committee whose preliminary report was approved at the last annual meeting.

I think that the time is ripe for an amendment of the Medical Acts and in my judgment the most pressing requirements are:—

1. Reconstitution of the Medical Council.
2. Increased Direct Representation.
3. One one-portal system of entrance to the profession.
4. The punishment of practice for gain by unregistered persons.
5. The regulation of medical aid societies.
6. The registration of obstetric nurses.

I am strongly of opinion that the representatives of universities and medical corporations on the General Medical Council should be elected by their respective medical graduates and diplomates or that the number of Direct Representatives should be largely increased and that a system of district representation should be established.

The fortieth clause of the Medical Act of 1858 requires to be so amended that practice for gain, and not assumption of title only, by unregistered persons should be made penal.

Increased power should be given to the Medical Council so that registered persons who accept appointments in medical aid associations, which exploit the public at the expense of the profession by advertisements and touting, could be dealt with rigorously.

I am *not* in favour of the registration of midwives as independent practitioners. I have always advocated the registration of obstetric nurses whose functions should be strictly limited and upon whom nursing duties should be imposed. I think also that the work of these registered women should be conducted under medical control.

The minimum age at which a medical student can be registered should be 17 years, and a uniform system of entrance examinations, under the authority of the Medical Council, should be established. The five years' curriculum after registration of studentship should be rigidly maintained.

Mr. Victor Horsley is among those of my friends who have strongly urged upon me the duty of offering myself as a candidate at this election, and I much regret that Mr. Horsley is, owing to the wording of the Medical Act, unable to resign and offer himself for re-election at this time. It would have afforded me pride and pleasure to be associated in the candidature with a man who has rendered such splendid service to the profession. If you elect me I believe that I shall act in complete harmony and concord with Mr. Horsley and other Direct Representatives in promoting what I think to be the true interests of the

profession—always the true interests of the public—and it shall be my constant endeavour to justify the confidence reposed in me.

Yours faithfully,  
Old Trafford, Oct. 28th, 1901. S. WOODCOCK.

TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—As one who believes it to be essential that the General Medical Council should undergo some radical alterations and improvements, and who trusts that he is to a considerable extent qualified to assist in the proper carrying out of these modifications, I am coming forward as a candidate at the approaching election. The foundation of my claim is that I believe that the General Medical Council should be essentially concerned with the welfare and interests of the general medical profession and the safety of the public, and not, as at present, only with trying to reconcile the various selfish interests and jealousies of the different corporations and licensing bodies.

The constitution, procedure, and finances of the Council require thorough revision, and the members must directly represent the profession—not the restricted councils of each corporation. The present unfair treatment suffered by our Direct Representatives must be met by sending resolute men who will not flinch from asserting the wishes and interests of the general profession, no matter how bitterly the vested interests oppose; and in some instances this opposition has overstepped the limits of mere bullying and become absolutely illegal.

It is especially in such circumstances, and also in the necessary amendments to the Medical Act and other legislation, that I hope my qualification of barrister-at-law may be of especial service to my fellow practitioners; and as I now am, and have been for over 15 years, engaged in general medical practice, I trust that the profession will recognise that it would be to their interest to avail themselves of the services which I now place at their disposal.

I am, yours faithfully,

CHARLES W. HAYWARD, Barrister-at-Law, M.D. Edin.,  
D.P.H. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.  
Liverpool, Oct. 27th, 1901.

MEETING AT BIRMINGHAM.

A large meeting of medical practitioners was held at Birmingham on Oct. 24th to hear an address from Mr. Victor Horsley, when about 120 attended at the invitation of the Birmingham and District General Practitioners' Union, a well-known and influential local organisation. The meeting was held in the large lecture theatre of the University, a fact which is evidence of a broad-minded spirit on the part of the authorities that might with advantage be imitated elsewhere. Mr. H. Langley Browne was in the chair and briefly introduced Mr. Horsley.

Mr. HORSLEY said that while there were many points requiring reform in the profession the outlook was brighter than when he joined the General Medical Council four years ago. Speaking of the question of contract practice, he earnestly warned the profession in any question of negotiations with the clubs to enter upon them only after the conditions had been defined. One such condition must be that of "wage-limit." The attitude of the General Medical Council was, he thought, very satisfactory on the question of contract work and medical aid societies. He desired as an example of this to allude to the Irvine case. By no means so satisfactory, however, as was shown in that case, was the attitude of the public towards the profession. No other learned profession nor either of the services would have been treated with the same indignity as the medical profession when the case of Dr. Irvine was mentioned in the House of Commons. That the Right Hon. J. Chamberlain should have insulted the profession by referring to their "trades-union" rules might be attributed to ignorance and faulty information, but that the medical Members of the House should not have made a better case was indeed surprising. The General Medical Council, in condemning Dr. Irvine, had in mind the flagrant advertising that was adopted by the Consultative Institute, and the medical profession had always exercised discipline in its own ranks, a thing he believed a trades-union never had done. Singular to relate, Sir W. Foster was the only medical Member to rise in the House when the honour of the profession was dragged in the dust, and even he did not explain the reason why Dr. Irvine was condemned for

"infamous conduct," but allowed the House of Commons to remain under the impression that the charge of infamous conduct was brought against Dr. Irvine simply on account of the lowness of his fee. No other medical man defended the honour of the profession and Sir Michael Foster even voted in the majority in support of Mr. Chamberlain. But what revealed the political impotence of the profession in the most striking light was the confession that Sir John Gorst was obliged to make, that although the General Medical Council was practically a department of the Privy Council, neither he nor the Duke of Devonshire had time to read the minutes. That, indeed, was "infamous conduct." But not only was the General Medical Council hindered in its work from above, it was also troubled from below. Recently the Colleges of Physicians and Surgeons, bodies with an ancient history but whose *raison d'être* had now disappeared and which were in financial low water, had disputed the ruling of the General Medical Council. They must be forced to give way. Mr. Horsley then referred to the question of reciprocity with Italy, and showed that in this matter also the Privy Council had entirely neglected the advice of the General Medical Council. The remedy for all these grievances was a new Medical Act, but he feared that the time for passing this was not yet. Meanwhile let medical men organise themselves into such bodies as the Birmingham and District General Practitioners' Union, and especially let them support the reconstitution of the great British Medical Association and their interests would no longer be neglected.

#### MEETING AT NEWCASTLE.

A meeting was held on Oct. 26th in the Library of the College of Medicine, Newcastle-on-Tyne, under the auspices of the various local medical associations, for the purpose of hearing the candidates for the forthcoming election to the General Medical Council. The summonses for this general meeting of the medical profession of the district round Newcastle were sent out by Dr. A. Cox of Gateshead and the various local medical associations must be congratulated on the results of his labour, for the number of medical men attending the meeting was about 100.

Mr. RUTHERFORD MORISON having taken the chair called on Dr. Cox to read some letters which had been sent to him.

Dr. Cox said that he had a letter from Dr. Glover who was the only one of the candidates who had not been able to attend. The letter was dated Oct. 19th and said that Dr. Glover was sure it would be understood that it was a great disappointment to him to decline all public meetings, as it was always a pleasure to him to meet his constituents even when they met to debate difficult questions. The letter concluded with a particular request to Dr. Cox to make the unavoidable reason of his absence clear to the meeting. Dr. Cox said he had also had a post-card in which Dr. Glover was very anxious to impress on his constituents that nothing but sheer necessity prevented him from attending. After Dr. Cox had read the names of several medical men who regretted their inability to attend he proceeded to say that Dr. Charles Hayward of Liverpool had allowed himself to be nominated as a candidate for the General Medical Council, but that the committee had not known of his intention in time or an invitation would of course have been sent to him to speak at that meeting.

Mr. MORISON said that he need not tell them what that gathering was for. It was to hear the views of those whom they hoped were going to represent them in the General Medical Council. Some of them remembered that the very name "medical politics" used to stink, but at the present day they had come to recognise that the subject was of great importance. They saw that without combination any body of men were absolutely helpless in this present age. Unless there was some combination there was no one voice speaking for the medical profession. Being without combination the medical profession had gradually got to be heard less and less, and its opinions had come to have less and less importance. They had, however, roused themselves to this fact, and they welcomed those gentlemen who had come there to tell them what they could on medical matters. In addition to the services medical men owed to the public they had duties to themselves as a combined body and to themselves individually. Owing to the courage and the ability with which Mr. Horsley had taken part in the debates of the General Medical Council they had arrived at the definite conclusion that changes in the General Medical Council were

very much wanted and that there were many things in its composition which would be better for being revolutionised. Mr. Horsley had taken a very active part in the work of the Council and they hoped for great things from him in the future. He would first ask Dr. S. Woodcock of Manchester to address the meeting.

Dr. S. WOODCOCK (Manchester) said it was a great pleasure to him to meet so many medical men in the north. He thought that they were beginning to regard the General Medical Council as a sort of medical parliament and to take an interest in the election of the Direct Representatives. Unfortunately there was no doubt that there was considerable apathy in the profession generally concerning medical politics and he was delighted to see so many medical men assembled there in Newcastle, especially on a Saturday afternoon. In Manchester a Saturday afternoon would have been the very worst time on which they could have hoped to get together a large meeting, for in that district they were somewhat strict Sabbatarians, and they got as much work done on the Saturday as possible so as to relieve themselves on Sunday. Dr. Woodcock, continuing, said that his view with regard to the General Medical Council was that it was lacking in the qualifications which he thought a Council affecting to provide for the interests of the public and the profession ought to have. Its constitution was, in the first place, such as to make it unlikely that it would take any very great action on its own part for reform. It was a sort of compromise which was effected because the medical corporations could not agree among themselves. He remembered that the Apothecaries' Society was not anxious for any reform which would deprive them of any of the monopolies that they enjoyed, and that was also the case with the Royal College of Surgeons of England; the Royal College of Physicians of London was jealous of the rising influence of the London University. In consequence a body was formed which was representative, in the first place, only of the medical corporation and their representatives were men not elected by the graduates or diplomates of those bodies, but by small coteries, the result being that they constituted a Council which was in no sense a representative body. Some years after the constitution of the General Medical Council they procured an amendment of the Medical Act which gave the profession a very few Direct Representatives which was a miserably inadequate concession to the demands of the profession. He, however, did not hope for very much reform from the General Medical Council; he did not anticipate that it would do much to encourage reform until the Council had been reformed itself. In the first place the Council should make a recommendation to the Privy Council that the number of the Direct Representatives should be increased as far as possible. While doing that it should be suggested that they should have a topographical arrangement for the election of the Direct Representatives. It was bad enough for those men living in the North of England as he was described as doing to have to travel 150 miles to meet his friends in Newcastle, but the candidates from London had to travel double that distance, and Mr. Jackson from Plymouth three times as far. If medical men were to be induced to take part in the elections of the representatives they should be afforded a fair opportunity of seeing and hearing those gentlemen who aspired to represent them in the General Medical Council. If he (Dr. Woodcock) was only obliged to appeal to those medical men resident in the north—as, for instance, those in York, Leeds, and Bradford—it would be possible for him to make their acquaintance and personally to make his views known to the men in those thriving places. Dr. Woodcock then proceeded to point out that there appeared to be a disposition on the part of one or two Royal Colleges to be in dispute with the General Medical Council with regard to the question of the preliminary examination. He thought it was a point of the utmost importance, though he was uncertain himself whether the General Medical Council had much influence over preliminary examinations. He considered that they should see to it that those who were entering the medical profession should have a good sound education, as he believed that the want of such preliminary training was to some extent the reason why the profession was not held by the general public in such respect as perhaps it ought to be. At the last Council meeting of the British Medical Association they passed a series of resolutions concerning this question of preliminary education and he would like to read them to the meeting and to say that they represented

very accurately and very faithfully his judgment on this matter. The resolutions were proposed by Dr. P. Maury Deas of Exeter and were seconded by Dr. E. L. Fox of Plymouth. The first was that it was undesirable that anyone should be registered as a medical student until he or she had attained the age of 17 years. The next was that the standard of the examination in preliminary general education required by the General Medical Council should be suitable to candidates of 17 years of age of average intelligence and reasonable industry. The third was that the present system of multiple examining boards was most undesirable and that it was necessary in order to secure uniformity of standard that a single examining board should be appointed by the General Medical Council and that this board should hold its examinations as often as necessary at multiple centres simultaneously. The fourth was that the examination should include at least Latin, mathematics, English grammar, literature and essay writing, history, geography, and either French or German. The last was that a committee of the Council be appointed to consider the whole subject of preliminary general education and the best means of promoting the carrying into effect of the foregoing recommendations, and to report. He thought that those were most desirable resolutions and it was greatly in the interests of the public that they should be passed. They saw that they were in some respects fighting for the very reforms which the early medical reformers were fighting for more than half a century ago. There was the necessity of having a one-portal system, for they had about 20 qualifying bodies. There was the necessity of having an amendment of the Medical Acts under which they could punish a man for practising without being registered. At the present day they found men practising with impunity unless they assumed medical titles. The General Medical Council had no control over unlicensed people. The General Medical Council had practically abolished the unqualified assistant and they did it by getting at his principal. They said, We shall punish you if you employ an unqualified man. It so happened that a man had an unqualified assistant who was a very sharp fellow and when the decision of the General Medical Council was issued the assistant was asked what he was going to do. "Oh," he said, "I am going to continue practising; I shall not call myself a surgeon but I shall practise all the same." That man was still practising, and such a thing was quite possible under the Act as it now existed. A surgeon was prosecuted for a criminal offence and was imprisoned for 12 months. When that man came out of prison he put his name up and practised with such a success that might excite envy, for he left £50,000 to a university. That was, he thought, an illustration of the fact that the present law only took cognisance of the assumption of medical titles and in reference to that he was speaking to a Member of the House of Commons one day when he was up in town on another question in connexion with medical reform. He was talking to this Member about the prescribing druggist and he was told that it was not possible to touch him because one half of the Members of the House of Commons would not hesitate to go into a druggist's to have a pick-me-up as they went along. They would see that that was one of the difficulties under which they laboured. The time, however, was ready for some reform to be effected and it would be no less in the interest of the general public than in the interest of the profession. He (Dr. Woodcock) thought they ought to hold on like grim death to the five years' curriculum and he thought that five years was quite short enough time for any young fellow with a good preliminary education to lay hold of the knowledge which was necessary to embark him in the world as a practitioner of medicine. Now there was a question which perhaps excited a good deal of interest lately—that was the question of medical aid associations, and they had rather a striking illustration of the ability of the consultants to deal effectually with a man when he trod on their corns. He referred to the case of Dr. Irvine at Birmingham who was connected with a sort of medical aid association and who began practice as a consultant of that association. He had never seen such a fluttering among the pigeons as there was in that affair, but he would remind them that the very same sort of thing had been going on, though with men of smaller calibre. When brought before the General Medical Council they made short work of Dr. Irvine, but the issue of that affair revealed that the General Medical Council did not stand high in its relations with the Government, for in the debate in Parlia-

ment on the appointment of Dr. Irvine as one of His Majesty's inspectors of schools Sir John Gorst, representing the Government in the House of Commons, said with a sort of scorn that he did not read the minutes of the General Medical Council and was not acquainted with what went on in the General Medical Council. Neither his noble friend, the Lord President of the Council, nor he himself had sufficient leisure to acquaint themselves with the proceedings of the General Medical Council. And that body, continued Dr. Woodcock, was supposed to be the one which was charged with the responsibility of advising the Government in regard to medical matters. It revealed the fact that the General Medical Council was a subordinate body which was under the control of the Privy Council. It only required two members of the Privy Council to veto any action of the General Medical Council. He did not know what could be done; he had no hope except by a general rising of the medical profession as one man against that sort of thing. They often wondered how it was that their forefathers were able to stand the condition of things before the reform of Parliament, but they had now at the present day an enormous constituency of educated men with many of them contented to remain under the conditions which he had described. He remembered a president of one of the Royal Colleges saying at a meeting of the British Medical Association when there was an agitation going on for reform that he did not think that any reform of the Medical Act of 1886 was wanted—it was a very perfect Act and there was nothing more to be desired. In fact, he considered that they were in the best of all possible worlds and under the best possible conditions. But the individual opinion of that particular person did not apply, for they had reason to complain that after all the money they had spent and the time and energy they had expended in equipping themselves to become registered practitioners they should get no further protection from the State than that of their title. In regard to medical aid associations he knew that the General Medical Council had no thought of power to issue an edict prohibiting men from accepting situations under these medical aid associations, but they had one power, and he believed they would exercise that power, and he thought he could trust the General Medical Council as long as Mr. Horsley was there to exercise it, and that was that if local organisations could get up a concrete case and give proof that any man had been acting for a medical aid association which touted and advertised then he believed that man could be dealt with by the General Medical Council. It was a shame that they had to do things in that way, but he believed that it was only in that way that it would have to be accomplished. Coming next to the question of the wage-limit Dr. Woodcock said that Dr. Glover seemed to be enamoured of what he called a conciliation board. Personally he did not mind a representative of the medical profession going on to a conciliation board to meet men who would meet their representatives in a conciliatory spirit. They had lately had some curious experiences in regard to this conciliation board. Dr. A. Cox was on a committee of the British Medical Association which met the representatives of the friendly societies, to whom it was said that in the first place it was necessary to have a wage-limit. But this demand was definitely refused and the friendly societies said, "We will not have a wage-limit." It appeared that

"The good old rule  
Sufficeth them, the simple plan,—  
That they should take who have the power,  
And they should keep who can."

What was the good, Dr. Woodcock asked, of the medical profession being represented on a conciliation board with men who were so entirely unconciliatory? Such a course of action would be simply giving the profession away until the representatives of the friendly societies came into a more reasonable spirit. In connexion with the wage-limit he recounted how a man came to him in Manchester last week who boasted of being a wealthy man and said that he only came to Dr. Woodcock when he was seriously ill, as a general rule going to his club doctor. On being expostulated with and told that being a man of wealth he ought not to take advantage of a club, he replied that that was all nonsense: he paid his money to the club and he ought to have something for it. Dr. Woodcock said he only mentioned that incident in order to illustrate to them that it was necessary that they should have some distinct understanding in

regard to the wage-limit. He would just say in passing with regard to the finances of the General Medical Council that Mr. Horsley had revealed that these were not in a very satisfactory condition. The branches of the Council had been living on the capital, and the Irish Branch Council had been going beyond that and had followed the advice of Artemus Ward, "Live within your income even if you borrow money to do it with." That was not a very satisfactory condition of affairs, and if the General Medical Council was to be a potent instrument strong enough to effect the purposes for which it had been constituted then it should have sufficient money. He could not escape, after serious thought, from the conviction he had that it would be a good thing for the medical profession if they had to subscribe an annual fee. If that were done the money would be provided and, reckoned at £1 a year for each medical man, would amount to about £35,000. Anyhow, that or some similar sum would have to be provided and it was certainly most unsatisfactory that the General Medical Council should be allowed to have its affairs get into a financial muddle. He thought that the penal powers of the General Medical Council ought to be modified: they had no punishment but a capital one, they could do nothing with a man but cut him off the Register. There might be conditions under which a man might be suspended so that he might be under observation as regards his conduct or he might be called upon to get some one to stand surety for him. He considered that there ought to be a little more elasticity about the law in regard to the punishment of men for infamous conduct in a professional respect. It would be desirable to have the penal powers of the Council so modified as to enable them to deal with some measure of justice with men proved guilty of the less serious professional offences. He was heartily tired of the midwives question, for after years of work they were still going on in the profession with a sort of internecine war. The battle went on week after week in the press. There were men on the one side who said that you should do this and there were men on the other side who said that you should not. He thought, after all, they would be obliged to look facts in the face. His position was this—that if they could secure a system whereby midwifery nurses could be registered, their functions limited in a decided and distinct manner, so that they could be punished for any encroachment, and if they had nursing duties imposed on them, and were placed under medical control as far as possible, he thought they should have come to something which could be accepted as an instalment. It would be tentative—all Acts of Parliament were tentative; but if they had to wait for something perfect it might perhaps come in his time or it might not. He was not in favour of registering midwives as independent practitioners. He believed that it was possible that a system of medical control could be arranged to prevent that and he would like such a scheme to be arranged for the satisfaction of everyone. It was a very difficult question. There were a great many men who were opposed to them, not from sordid reasons, but because they honestly thought that the alternative plan was in the interests of the community. He gave them credit for thinking uprightly on the question, but the time had come when they themselves should form a conciliation board and by means of that arrive at a practical solution. Burke said that compromise was not seldom the wisest course in politics, and nearly all the Acts of Parliament under which they lived and by which they were governed were the results of compromise. This internecine warfare over the midwives stirred up bad blood and created ill-will, for there was always a short way with those who dissented which was somewhat a peremptory one, for it was no argument to say, "Damn you, sir, I do not agree with you." He sincerely hoped that something would be done which would satisfactorily deal with the matter. By the raling of the chairman each speaker was limited to 20 minutes, but Dr. Woodcock said if he might be permitted one word more he would like to say one or two things which were not altogether impersonal. They did not know there in Newcastle, and he wanted to tell them, that he did not want himself to go on to the General Medical Council because of the honour which it would confer on him. He had had more honours conferred on him by his medical brethren than he deserved. He had been President of the Clinical Society in Manchester, President of the Medico-Ethical Society, and President of the Lancashire and Cheshire Branch of the British Medical Association. He was a Member of the Council of

the British Medical Association, and he was Chairman of the Parliamentary Bills Committee, and for years he had been engaged with Mr. Horsley in attempting to secure medical reform by working on sub-committees under the auspices of the British Medical Association. He had been lately assisting in the attempt to reform the constitution of that Association and he hoped that if that were effected they would find the Association to be an instrument through which they would exert pressure and operate not only on Parliament but also on the country at large. The time would soon come when they would find that those of them who were charged with the safeguarding of the health of the community would have some right for consideration at the hands of the community for whom and in whose service they spent their lives.

Mr. GEORGE JACKSON (Plymouth) said he was pleased to come there to express his views on those questions that were likely to arise in connexion with the General Medical Council. It was especially gratifying to him to see so many present at that meeting and it rather contrasted with the numbers at other meetings that he had attended. It looked as if the men at Newcastle took an interest in medical politics and that was a good sign because one of the great difficulties they had to contend with was the apathy of the medical profession. He believed that on the last occasion of the election to the General Medical Council only about one-third of the medical men voted on the question as to who should represent them in the Council. If people would not take any care of their own affairs they could not expect Jupiter to help them. It was quite certain that Parliament would not listen to representation unless there was a strong body of opinion expressed by the profession in a certain direction. He would like to refer to his address. In the first place, there was the reform of the Medical Acts so as to provide for direct representation of the medical profession in every case except the Crown nominees. In order to reform the Medical Acts they would have to reform the General Medical Council itself, and of course, as they knew, the members who represented the corporations were in such an overwhelming proportion and so outnumbered the Direct Representatives that nothing could be done as it should be done owing to the dead weight against them. He hoped that whoever were elected as Direct Representatives would act in unison, because that seemed to have been wanting during the last five years—in fact, there seemed to have been almost antagonism. To arrive at reform they must endeavour to secure more Direct Representatives on the Council. There were two ways in which that might be done: they might do it by reducing materially the representatives of the corporations, and he suggested that the corporations should be arranged in groups with a representative for each. In that way there would be an opportunity for increasing the numbers of the Direct Representatives, and in addition to that the members who represented the corporations should be directly elected by the members of those bodies. He took for instance the Royal College of Surgeons of England as it stood at the present time. It was a grievance that Members of the College had not the slightest voice in the College affairs and possessed no vote. He said that all the Members should have a right of voting because they were Members of the body corporate. The Members should have a right of voting for the representative of the College on the General Medical Council and the same was the case with the other corporate bodies. If they were reformed then other things would follow. In the second place he had said in his address that the standard of entrance examinations should be raised and the age of entrance limited so as not to be under 17 years. The resolutions which had been read by Dr. Woodcock as having been considered by the Council of the British Medical Association were first passed at a meeting of his own branch of the British Medical Association which was held in Devonshire. When Dr. W. Gordon of Exeter brought them forward he wanted to add the subjects of physics and chemistry, but the others thought that it would be better to leave these subjects to a later period. He did not think that the brain of a lad 16 years of age was capable of fully profiting by the proposed instruction. It had been, however, objected that at 16 years of age a boy could pass any of the examinations proposed. If there was a uniform examination such as was suggested any boy 14 years of age might pass it and then would waste his time till he was 17 years of age. Mr. Jackson, however, pointed out that in such a case a boy should be compelled to show evidence of having done work meanwhile,

as, for instance, at some technical school. The third point in his address was that the one-portal system of entrance should be secured by forming a board of examiners composed of delegates from the present examining bodies. It was important to have the one-portal entrance into the profession and one portal for the purely professional examination. It might be something in the constitution of English people, but they seemed rather to like to do things in an odd sort of way. They did not favour the idea of uniformity. In France and Germany they had one State examination which everyone had to pass. After passing that they could take any ornamental university degree that they pleased. In England the idea of freedom prevailed, but in the end they would have to come to the one-portal system. The General Medical Council was composed of such a number of representatives of corporations that it was not likely they would consent to the system, but it had occurred to him that it might be brought about by all the present bodies that examined sending delegates to a board of examiners so that everyone would have some finger in the pie, everyone would get some plunder out of the arrangement, and then the method of uniform examination might be instituted. Again, in any legislation for the reforming and alteration of the Medical Acts it was desirable that the Council should have power to suppress quacks who practised medicine and surgery under various forms of colourable pretence. Nothing could be done with the class of opticians and others under the present Act unless a man professed to be registered or called himself a surgeon or physician. The lawyers were much more careful of their own interests and if any man made a colourable pretence of being a lawyer or if a debt collector wrote a letter to anyone in the form of a legal document to collect a debt the lawyers were down on him and he soon found himself in a wrong position. In his opinion the General Medical Council should have a great deal more power in that direction. He considered that a more definite pronouncement should be made against medical men acting as medical advisers to clubs and insurance societies whose agents touted for members. The matter had become of late a very serious evil and Mr. Jackson described how the insurance companies tried to bribe people into joining. Their agents would say to a man that he could join as a sick member and could have a medical man of course, adding that he was a very good medical man. These agents also did not care how well off the people were who were to become members, the matter of the insurance was all that they cared about. At Plymouth they had attempted to cope with the evil; they had not appealed to the General Medical Council because there was no use in doing that, but they had applied to the Colleges which had licensed the medical men who were acting as medical advisers to these insurance societies. They found that the Irish Colleges were willing to take cases up and would write to the medical men to say that if they continued in that sort of action their diploma would be withdrawn. Mr. Jackson then came to the point that the General Medical Council ought to have supreme power in matters of general education. There was a sort of deadlock between the Royal Colleges of Physicians of London and Surgeons of England and the General Medical Council in regard to the five years' curriculum. The Royal Colleges were losing their candidates for their diploma, so they said, that the candidates might attend the first of the five years' curriculum at one of the higher grade board schools or technical schools. The General Medical Council said that the five years should be spent in a medical school, but they had no power to say to the Colleges that they must do as they told them. The Colleges could defy them, but in a new Act a clause should be put in giving the Council powers. He then came to what he had referred to as the burning question of the time—the midwives question. He thought Dr. Woodcock had said in a former speech that they had always had the midwives; but they had always had many people who were not desirable, and he thought if they could they ought to try to extinguish the midwives. Why should they always have these Sarah Gamps? Every medical man knew what an extreme danger they were, what an enormous number of deaths they caused, and every now and again they saw reports of the carelessness of these women. England was a free country, but it was going too far to allow these people to endanger the lives of those who were most important to the country. The population of England was not increasing as it ought to, and it was necessary that the mothers of the country should not incur these dangers. He thought they ought to try to extinguish

these Sarah Gamps altogether. He thought he was right in saying that the Bills which had been introduced into Parliament had laid down that any woman who had been in practice as a midwife for two years should be entitled to be placed on the Register. He protested against this right being given to any dirty woman who happened to be a midwife, and contrasted the proposed law with the provisions of the Medical Act on the construction of the Medical Register. He thought that the striking out of the clause might be a little hard on some of these women, but if they registered them they would at once assume other duties of a more important character. He thought it was very desirable that the question should be settled, and if it were possible a Bill should be introduced into Parliament to register all nurses who had had a sufficient training, that is to say, a three years' training, and the nurses who took midwifery cases should be under the control of medical men. For many years the Government had insisted on the guardians of the poor providing medical assistance, but they did not insist on their providing nurses except in the case of workhouses and infirmaries. It was a sad thing to treat midwifery cases in the homes of the poor nothing was done that should be done, there was no cleanliness, and he thought it was very desirable, if nurses were provided, to see that treatment was properly carried out under the immediate control of medical officers. He had been told at a meeting at Liverpool that that course was followed at Saddleworth, but if the guardians did it they did it as an act of grace. He did not think it was possible for them to meet the promoters of the present Midwifery Bill because their views were so different. One of their views was that it would give more employment to women and that was one reason why they advocated that Midwives Bill. Another thing was that many people liked to be charitable at other people's expense and there were many ladies who liked to be philanthropic without cost to themselves at the expense of the medical profession. It was, of course, very easy to be philanthropic when it cost nothing. In regard to the clubs he was not a believer in the conciliation board that Dr. Glover thought would be of so much value. He found that it was the opinion of all medical men with whom he had spoken that the working man would not listen to the question of wage-limit. They would not entertain that point at all, so he could not see that it was any use entering into the matter with them. In those places where the working man would not make any concession the best plan for the medical man was to provide provident dispensaries run on proper lines. They had a small one in Plymouth run in that manner, the management of which was in the hands of the local branch of the Incorporated Medical Practitioners' Association. They had a wage-limit and the system worked well. If the management of a provident dispensary was in the hands of those who were doing the work, as, for instance, in the hands of the council of medical men of the local branch of the Incorporated Medical Practitioners' Association, he did not see that there could be anything which would go very wrong in the matter. If, however, the management were to get into the hands of a lay committee they would exploit the medical men. At Coventry there was a large dispensary to which half the population belonged and the staff would not do anything to endeavour to abate the evils in the system. He supposed they were afraid of losing their appointments and the committee would not submit to any inquiry as to the amount of wages earned. They said that they did not allow touting, but if a sick man wished to join it was possible for him to do so by getting two healthy persons to join with him, and Mr. Jackson explained how that was nothing else but touting. They had had two or three attempts at the meetings of the British Medical Association to have the matter dealt with, and the men concerned had been remonstrated with, but without avail. If the General Medical Council would pass a motion that it was infamous conduct in a professional respect to act in that manner it would be easy to deal with it. The men could then say that they could not do that sort of thing because the General Medical Council would strike them off the Register, and then the committee would have to give way and submit to a wage-limit. He (Mr. Jackson) was asked the night before at Liverpool to say how he would introduce a Bill into Parliament dealing with medical matters and his answer was, "Through the British Medical Association." The Association was in course of reconstruction and the system of delegation was going to be tried. The first meeting was to be at Manchester, and if the Bill was formulated by the Council of

the Association and thrashed out by the delegates there would be no difficulty in getting such a Bill into Parliament. The Bill would be the means of educating Members of Parliament in regards to medical matters and without that they would get nothing done because Members of Parliament did not care unless pressure was put upon them. What they said was that no one ever wrote to them about medical matters, and unless they all individually took the trouble to put pressure on the Members of Parliament the legislation they sought would not be secured. Mr. Jackson concluded by thanking the meeting for the kind way in which they had listened to his remarks.

Mr. GEORGE BROWN (London) said that before leaving town for the north-west to meet his constituents he took the advice of a well-known and most enthusiastic medical reformer as to the line which he should take in addressing those among the medical practitioners who did him the honour of coming to hear from him an account of his stewardship. His friend said that he did not think he could give him better advice than as follows: "When you go north tell them what you promised to do if elected and then go on to state how far you had endeavoured to carry out those promises, and, thirdly, as to what you should aim at in the future if it met with the pleasure of your constituents to re-elect you to go back to the General Medical Council." He thought that was very sound and proper advice, and he would have followed it most closely were it not that during the preliminary stages of the contest he had been met with some attacks of a personal character, and he felt from what had taken place at Liverpool that it was only right that he should address them on some of the personal points connected with his position in the General Medical Council. He had not expected to have to do this, but when he was attacked—and attacked unjustly—he thought that it was his bounden duty to reply to any attacks of that kind. The attacks he referred to he need scarcely dilate upon to those who were present at the meeting at Cheltenham. They would remember that those who had announced themselves to be candidates for the next election to the General Medical Council were asked to address the members of the British Medical Association at a morning meeting upon the matters connected with the General Medical Council. It so happened, taking, he supposed, the candidates in alphabetical order, that he (Mr. Brown) was called upon to be the first speaker. He said, then, that he would avoid personalities and he carried out his promise, but Dr. Glover who followed him made an onslaught on him which took him very much by surprise. However, the exigencies of the meeting did not admit of the chairman allowing him an opportunity of giving an explanation of the charges brought against him and therefore he reserved his remarks on them until he came on some public platform so that he could repudiate those charges concerning his conduct. As an old friend of his he had loyally supported Dr. Glover on many occasions and he was exceedingly sorry that he had not an opportunity of meeting him there on that occasion to refute those charges. Those of his audience who had read the medical journals might perhaps remember that the charges were of such a grave character that one of his strong supporters at the last election, now resident in Liverpool, stated that if the charges were true Mr. George Brown was no longer a fit and proper person to represent the profession on the General Medical Council. It was those charges that he would ask the indulgence of the meeting to discuss, and when he had met them he felt sure they would acquit him of everything like dereliction of duty in regard to the matter. He must remind them of what occurred at the Cheltenham meeting by reading from the report to them. Referring to the Midwives Bill and the granting of the so-called diplomas to midwives, Dr. Glover said, according to THE LANCET—a journal with which Dr. Glover had been connected for many years, and he (Mr. Brown) thought they might consider it a true report—Dr. Glover said: "Some gentlemen think that we should punish the leaders of the Obstetrical Society of London, and we have only one punishment and it a capital one, that we should remove their names from the Medical Register. Does any gentleman think that the most advanced medical reformer—Mr. Brown himself say—would venture to rise seriously and make a definite proposition to that effect in the General Medical Council? To do Mr. Brown justice I must say he has had the chance of doing this any time in the last five years and he has not

done it." That charge almost took his breath away because he had a sort of dim recollection of having done it, although Dr. Glover appeared to have forgotten it, and in that matter he thought Dr. Glover's memory must have failed him entirely. He did not think Dr. Glover would have knowingly made such a grave charge as that and he must have forgotten a circumstance which occurred on Nov. 29th, 1899, 18 months before he made this charge, and which was also reported in THE LANCET. The report stated that:—

The first business on the agenda was the following notice of motion by Mr. Brown—namely: 1. That notwithstanding the resolution of the Executive Committee passed on May 27th, 1895, the Registrar be instructed to inform the President of the Obstetrical Society of London that the Council can no longer assent to the holding of examinations in midwifery or to the granting of certificates of proficiency in the practice of that art by any body of persons unless invested with legal authority to hold examinations and grant certificates in this branch of medicine. 2. That the Registrar be instructed to insert notices in the leading medical journals to the effect that on and after the first day of January next any registered practitioner who takes part in any examination in the art and practice of midwifery or any other branch of medicine or surgery held by or on behalf of any society or person or body of persons, unless legally authorised to hold such examinations and grant certificates of proficiency to successful candidates, will be liable to be adjudged guilty of infamous conduct in a professional respect and to have his or her name removed from the Medical Register.

What became, then, of Dr. Glover's charge in the face of that—that he (Mr. Brown) had never taken any steps whatever to induce the Council to regard those actions as infamous conduct in a professional respect? He considered that what he had read was a sufficient answer to the charge. He might say that he was supported on that occasion by his colleague, Mr. Victor Horsley, who made a strong speech in seconding those motions of his. He (Mr. Horsley) seconded them and further stated, though he did not know whether Mr. Horsley remembered it, that "they must all have the utmost sympathy with the society in instituting this examination in the first instance, but while that was so they could not but feel that they were mistaken in issuing the certificate of any kind which, as the resolution of the Council said, was a colourable imitation of a diploma. He submitted that the present certificate contravened the spirit of the Medical Acts and was calculated to deceive the public." Dr. Glover in his speech, which Mr. Brown said was of course against the motions, asked if he (Mr. Brown) would strike off from the Register Sir John Williams, Dr. Champneys, and Dr. Cullingworth for issuing these certificates. Mr. Brown said he certainly would, and he would treat Sir John Williams and any others, high as they might be in the medical profession, the same as he would the latest addition to the medical profession if he should do an illegal act contrary to the letter and also to the spirit of the Medical Act which they lived under, and if he should continue to do it after he had been warned he would deserve to be struck off the Register. He (Mr. Brown) thought that it was a position that every medical man who had his profession at heart would agree to. The next charge, Mr. Brown said, that Dr. Glover had brought against him was more serious because it affected a question which touched them more closely, and that was in regard to the motion which he brought forward concerning the medical aid associations whose agents canvassed from house to house for patients. He had received in regard to the midwives question many communications but he had received a far greater number regarding the sweating of the profession by the medical aid societies, in the proportion of three or four to one. The charge which Dr. Glover brought against him was practically that he brought forward before the General Medical Council matters upon which he could not get a seconder—matters which laid him open to ridicule, as if the members of the Council said, "Oh, Brown again, Brown again," and then dismissed the affair. It was true that he (Mr. Brown) brought forward a motion referring to the medical aid associations concerning which Dr. Glover said at Cheltenham: "Mr. Brown tried to counsel the Council to do something more drastic and did not get a seconder." Mr. Brown said that he had been in correspondence with many local medical societies in various parts of the country, including the district of Newcastle, and he had been urged to lose no time in bringing that matter before the General Medical Council. The Middlesbrough Medical Society were memorialising the Council that it was felt that the holding of appointments under such medical aid societies as were referred to was derogatory to the profession, and if the Council did not discountenance the practice it would

very seriously affect medical men who had resigned appointments connected with such societies. Mr. Brown accordingly proposed at the meeting of the General Medical Council on June 11th, 1901, that

Notices be published by advertisement and otherwise to the effect that association with medical aid societies and clubs which systematically canvass for patients will be regarded by the Council as infamous conduct in a professional respect, rendering any practitioner proved to be guilty thereof liable to have his name removed from the Medical Register.

Mr. Brown said that any person with common sense would recognise that in an administrative body of 31 members all sitting there sent as representatives to represent such a learned profession as medicine, to maintain its honour and dignity, that out of those 31 members if one of them proposed a motion which he thought was conducive to the best interests of the profession and could not out of that body get a seconder, that man must be a crank and that he must be doing something not to the interests of the profession. He (Mr. Brown) had proposed that motion in fulfilment of a mandate from his constituents. It was a motion that had been discussed in London by the Council of a recognised institution and he had brought it to the General Medical Council and he had hoped that out of that body there would have been someone who would have supported him in saying that that was a desirable motion to carry. He was not ashamed of the fact that he could not get a seconder, he could only say that he was sorry he was unable to do so. He believed that the time would come when that motion would be proposed at the General Medical Council and would meet with a seconder, and he also believed that that motion would be carried. That motion, however, would not be carried if the medical profession left it only to Mr. George Brown and Mr. Jackson if they were elected, but it would have to be carried by the profession themselves putting their shoulders to the wheel and sending up memorials to the Council and giving them to understand that they were seriously intent on the matter. He trusted that they would agree with him that that motion must be brought forward again, and he hoped that it would meet with a seconder and supporters. He was confident that it would not be thrown up to him by his colleagues again that he proposed motions which he could not get a seconder for and thus brought direct representation into contempt. As long as they instructed him to do those things he would do them. He had no personal interest in medical aid societies because he had not had anything to do with clubs for more than 20 years. He was one of those who did not believe in conciliation boards in any matter between a medical man and his patient. Such boards were a delusion and a snare and would only land them in disgrace and difficulty. They could only settle that matter by working in unison; by being true to one another they could carry out their club practice and contract work without any assistance from any Conciliation Board of the General Medical Council or any other body. As to what he (Mr. Brown) had promised last election it would not be necessary to dilate upon it because most of those present belonged to that district and were ardent reformers—at least, they were more ardent than those in other parts; at any rate, he got more letters from the north which were of assistance to him than from elsewhere. The position was one of extreme difficulty; the Direct Representatives only numbered five out of 31, and all that they could do was to keep pegging away. The points that he alluded to in his address at the last election were about five in number. One was that he would do what he could to reform the Medical Acts. They had not been able to carry a Medical Reform Bill, but that he hoped would come. It had been impossible to get the General Medical Council to take any action in that matter. It must be done by a great organisation such as the British Medical Association, and it must be put before the House of Commons and well supported and then they would have a Medical Reform Bill. But he was afraid that they would not get all they required; he did not think that the Government would give them such stringent powers as they would like to have in order to stop unqualified practice, or such powers as the public ought to give the Council for their own protection. They had stopped the practice of the unqualified assistant, and in his experience of 30 years as a reformer he had found that the mill for turning out unqualified practitioners was the use of unqualified assistants by practitioners. When an unqualified assistant was discharged he, having so many patients who knew him in the villages and towns about, felt that he could practise on his own account and so developed

into an unqualified practitioner, and that is how they had been manufactured by the score all over the country. By preventing the use of the unqualified assistant in visiting, &c., the Council had done a great deal to stop unqualified practice. In regard to preventing sick clubs and dispensaries from canvassing he had told them how he had been supported, and he could only regret that he could not report any good results except a pious resolution which had not done much. His friend, Dr. Woodcock, had just stated that if local practitioners would get up a case and present it to the Council and prove it the Council would take drastic measures as they did in the Irvine case. But he (Mr. Brown) did not think that it was at all a proper thing to ask medical men who paid a registration fee to the Council to be asked to take such a course. It was not right to ask medical men to go round making up cases against their local brethren after the manner of a detective. It was the duty of the Council to issue such regulations that that evil from which medical men suffered should be put a stop to without forcing them to adopt such a course as had been suggested. If the object could be gained by the issuing of an order from the General Medical Council that these appointments must not be held by medical men the whole business would be settled. They had just been told in regard to the Midwives Bill that they must come to a compromise, that they must give away something. He (Mr. Brown) did not believe in compromises: the thing was right or it was wrong. If it was right that these midwives should be registered as practitioners of midwifery they must let them be registered as practitioners, for midwifery was a branch of medicine and was within the four corners of their Bill of 1886. He said that it was their duty to themselves, to their profession, and to those who followed them to retain that charter unbroken. Why should they cut off the practice of midwifery and say that the midwives might practise that branch of medicine? Dr. Woodcock said that they should do it because midwives existed, but bone-setters and herbalists existed and counter-prescribers also. We should have no persons registered who were not properly educated to practise the whole range of medicine as well as any branch thereof. It was no unreasonable thing to ask the House of Commons to maintain the Act of 1886 intact. Referring to the question of geographical representation Mr. Brown pointed out that at the last general election Mr. Jackson was a candidate in the south, Dr. Rentoul in Liverpool, and he himself in London. He and Dr. Rentoul were honoured by being returned. Mr. Jackson was not, but received over 4000 votes. The principle of geographical representation was thus recognised at that time. It came with bad grace from Manchester to say that they were not represented topographically because the Lancashire and Cheshire Branch met when Dr. Rentoul of Liverpool resigned his seat and selected another member of their branch as their nominee to succeed him—viz., Mr. Horsley, although resident in London. He was glad that Mr. Horsley was selected because he had been a tower of strength to them. The only thing he would have liked to have further was for Mr. Horsley to be a general practitioner and if he were one they could not possibly have a better representative. Before leaving the question of topographical representation he would say that when Dr. Rentoul resigned he (Mr. Brown) felt sure that no one in the south would have stood in the way of Dr. Woodcock's election had he been selected by his branch instead of Mr. Horsley. Now when there were only two seats vacant it was not treating the present representatives fairly to put forward the principle of topographical representation. He had fought for them for 15 years and it was not fair after that to be told that he ought not to sit in the Council because he lived in London. They would have candidates from all parts of the country and medical men would exercise their judgment and elect those they thought most capable. Certainly if he thought it would serve their cause better to take a house and reside part of the year in Manchester, in Durham, or in some other part of England he would be very happy to do it, but he did not think that it would make any difference in the manner in which he would represent them. He was happy to have been able to answer the charges that had been made against him.

Mr. VICTOR HORSLEY said he appeared there under rather extraordinary circumstances, because when he was elected at a by-election he intended to present himself at the next general election (with the hope of re-election) for the

purpose of saving the profession the expense of another by-election; he was unable to do so since about a fortnight ago he discovered that it was legally impossible for him to resign and stand again. Therefore he was unable to resign his seat and he was unable to appear before them as he had hoped in the guise of a candidate. But for all that he trusted they would allow him to regard himself as though he were a candidate and to give them an account of his stewardship for the four years during which he had sat at the Council at their pleasure. He did not second Mr. Brown's motion for the reason that as regarded the General Medical Council it was *ultra vires*. The Council had no statutory power to do what Mr. Brown asked it to do, and therefore he secured no seconder. As regarded the principle of Mr. Brown's motion he would like to say that he was absolutely at one with Mr. Brown. He thought it was right that if the General Medical Council was going to make anything like a new departure in penal legislation, in which they had absolute power, they should signify the same to the profession by a resolution. But the Act of Parliament conferred on the Council no power to pass such motions: if passed they would be illegal, and he was not going to second any motion of which he was not quite satisfied in regard to its competency. During the last five years a change had occurred in the attitude of the Council towards their profession, and he saw that now in 1901 things were extremely different to what they were four years ago. The members of the General Medical Council had been chiefly reinforced, oddly enough, by young men and the ideas of the Council had become more progressive in consequence. At any rate, the general feeling of the Council was much more sympathetic towards the profession at large, and especially towards those in general practice, than it was when he first joined it. Mr. Horsley proceeded to sketch out the lines of improvement in the procedure and act of the Council. During the last four years they had completely reformed the legal work of the Council. The late solicitor had resigned after that very critical case known as the Hunter case. The solicitor having resigned they had fortunately obtained the services of the solicitor to the Royal Courts of Justice, Mr. Winterbotham, a gentleman who had shown already how deeply interested he was in their work and how anxious he was to follow out every point, so that they should never come near a recurrence of such an awful scandal as that of the Hunter case. For some years the finances of the Council had been in a hopelessly rotten state and for three years he had tried to obtain at least an inquiry into their financial condition and into the measures that were necessary to put them into a stable state. At last they had arrived at that point, but not without the most extraordinary misunderstandings on the part of Mr. Bryant the treasurer, and worse misstatements on behalf of the officials by their regular spokesman, Dr. MacAlister of Cambridge. All he (Mr. Horsley), could say was that in spite of every effort to hush up the truth concerning the financial position of the Council, efforts in which even the device of moving the Council into secrecy had been resorted to, a device which to his mind was absolutely incomprehensible on the part of a body of English gentlemen who had to deal with public money. It seemed to be rarely remembered that the only money the Council worked with was public money—that is to say, the money which practitioners paid on registration, from which moment such money became the property of the nation, and all accounts connected with it had to be laid on the table of the House of Commons and were not legal until they had laid there for the statutory period. He showed in 1898 that those account sheets which were laid before the House of Commons were false, but, as usual, the officials of the Council endeavoured to suppress him. Now, however, he had been fortified in his action by the report of the financial expert, Mr. Frere, whose advice had been sought. Now, at least, he hoped they would have another argument for altering the Medical Acts, because such alteration was absolutely essential if they were to reorganise the finances of the Council. The point was illustrative of the way in which the work of the Council had been done in the past and it was also illustrative of the fact that they could always hope to get reform in the future. Reference had been made by Dr. Woodcock to the most important question that had really affected the profession during the last 10 years, because for all that period the General Medical Council had been living in

a fool's paradise as regarded its real position towards the Government of the country. The Council was an intermediate body; it could not, of course, have any power over individuals of the kingdom, the members of the nation, it could not have any power over them of a kind which the central Government alone possessed. Therefore by the Medical Act the General Medical Council was placed under the Privy Council. As far as professional matters went the decisions of the General Medical Council were absolute, but when they came to matters of State policy the Privy Council intervened. For the last two years those of them who had followed the acts of the Privy Council in regard to the profession had seen with dismay that something was going on in the office of the Privy Council which was absolutely hostile to the general medical profession. Some influence was at work. Sir William Turner, the President of the Council, had repeatedly asked them to allow him to manage this or that piece of business by his personal intervention, and the Council had constantly placed such business in his hands for transaction by his personal action at the Privy Council. He had done his best, but what were the results? And they could only judge by results. He would take the midwives question as an example. The General Medical Council had laid down 10 points as absolutely essential in any Midwifery Bill. These were constructed during his services and those of Mr. Brown on the committee concerned, and he thought those 10 points were satisfactory, and that if they studied them they would see they absolutely safeguarded the interests of the public and the medical profession. Those 10 points were taken to the Privy Council Office. What was the result? The Duke of Devonshire, the President of the Privy Council, had on the most serious of those points gone back upon the Council, and that in spite of the fact that he had told a deputation of those who supported Lord Balfour's Bill that that deputation was to settle matters with the medical profession, and intimated that the General Medical Council was the mouthpiece of the profession. The system of negotiation thus only ended with the betrayal of the General Medical Council. Next, he would take the case of practice in Italy. Practice in Italy had been difficult in recent years, so their fellow-countrymen found out there, because the Italian Government wished to impose restrictions on them. They applied to the Government here to apply reciprocity. By the Act of 1886 the Privy Council could issue an order which became the law of the land that there shall be reciprocity between this country and a colony or a foreign country in regard to medical practice. The Privy Council, however, referred all the documents to the General Medical Council. On this the General Medical Council nearly had all its freedom and liberty of speech taken away from it by its Executive Committee who without the slightest authority wrote to the Foreign Office in favour of the proposal. That, however, they rectified at a subsequent session. First came the question whether it was in any way possible to institute reciprocity between England and Italy, and many of them showed in the Council that it was impossible. Some of them carried a motion which was to be embodied in the form of a letter to the Lord President of the Privy Council indicating the impossibility of this proposed reciprocity. This letter was actually before the Duke of Devonshire when suddenly an order in Council was issued that this reciprocity was to be established. So that the General Medical Council was wholly ignored, snubbed, and despised through this system of government by the Privy Council. Sir John Gorst, the Vice-President of the Privy Council, in referring to the case of Dr. Irvine before the General Medical Council, used these words in the House of Commons. He said concerning the appointment of Dr. Irvine as an inspector of schools that "at the time the appointment was made my noble friend the Lord President of the Council and myself had not heard of this charge against Dr. Irvine. (Opposition cries of 'Oh!') How could they have heard of it." Sir Walter Foster rose in his place, and he must have been surprised at the remark because he had been a member of the General Medical Council, and said, "You receive the minutes of the General Medical Council at the Privy Council." Sir John Gorst replied: "Neither my noble friend the Lord President of the Council nor myself have sufficient leisure to acquaint ourselves with the proceedings of the General Medical Council." He (Mr. Horsley) thought it was the most disgraceful transaction that ever occurred. He had said so at Birmingham, and it was duly reported in the *Times*. It was the most disgraceful

transaction that they could conceive of. Here was this Privy Council that had been communicating with them for so many years, and yet both the President and Vice-President of the Privy Council denied that they knew anything at all of the matter on which they had issued orders, &c. What, then, became of the letters sent to the Privy Council? what was the meaning of the letters received from the Privy Council signed by "Devonshire"? To his mind it was one vast farce from beginning to end. They were all agreed that there must be a new Medical Act. In the last four years they had driven home to the members of the General Medical Council the fact that there must be a new Act, but, as Dr. Woodcock had said, and he was glad to hear Mr. Jackson repeating that view, the only way was by remodelling the British Medical Association, by making that a truly representative body and having a representative meeting. So long as they brought together men from all parts of the country representing local practice and secured the support of that meeting in procuring a Medical Act Amendment Bill he knew that they would carry it in the House of Commons, provided they showed first the necessity for the reform of the General Medical Council and, secondly, that they had given a *quid pro quo* for the protection of their practice in the shape of enforcing the curriculum. Lastly, he wished to take the opportunity of repeating what had been said constantly elsewhere, that all these reforms that they wished to see carried out were presented to the judgment of the public as though they were designed solely for the benefit of the medical profession. That was a stupendous mistake. He would first get rid of the mistake that Mr. Chamberlain made in that same debate which he had referred to in the House of Commons where he alleged, quite under a misapprehension, that Dr. Irvine had infringed what he called a trade-union rule of the medical profession. Mr. Chamberlain asked, "Does the honourable gentleman say that to take lower fees than are usual is infamous conduct?" There was not a word in the debate from the beginning to the end of the true gist of the charge against Dr. Irvine—namely, the advertising and the touting which the General Medical Council held was infamous conduct in a professional respect. The public regarded the monetary relation of the medical profession purely in a commercial manner. They thought medical men wanted to sell in the clearest market and naturally they tried to buy in the cheapest and hence had arisen much misunderstanding. If they could only get the public to understand that the profession considered it a disgraceful thing for a professional man to undertake to attend an impossible number of patients—i.e., to undertake to treat these people honourably—then he thought the public would come into line with the medical profession. That was the way in which they ought to convince the public and the friendly societies that their motives were quite disinterested in that respect. In regard to the commercial side of the matter he thought they had a perfect position towards the public simply from this point of view, speaking now not of medical aid work but of ordinary contract practice, and that was that if the circumstances of the social life became more expensive of course it was reasonable that everything should rise in the same ratio. Next, in regard to the question of midwifery registration and legislation. The interest of the public demanded that the Sarah Camp should be got rid of. The public had no intention, so far as he could see, to get rid of midwives nor did he think it was possible to do such a thing as had been suggested. The true facts about the midwives had never been explained to the public. The public laboured under the impression that a midwife could practise *midwifery*, and that impression had been distinctly fostered by the action of the Obstetrical Society and some leading gynaecologists. He thought that such persons merited being struck off the Register for misleading the public and distinctly suggesting infringement of the Act of 1896. They had to tell the public that a midwife was not a fit person to practise midwifery and that if she did attempt to do such a thing she ought to be punished. It was for the protection of the public that the midwives should not be allowed to practise midwifery and that these women should be punished for doing anything in the way of an operation, and it was in the interests of the public that they should be when in work under the control of a medical man. Those points seemed to be steadily concealed from the Members of the House by those who advocated Lord Balfour's Bill. Unless the medical profession watched that matter very closely when that Bill was re-introduced the penalising clauses would be dropped out. He happened to

know as a matter of fact, curiously enough, that those same penalising clauses were probably the chief means of the Bill being withdrawn. Another important question, that of death certification, was so wrapped up with quackery and unqualified practice that it was a point upon which the public could not think that they were solely actuated by selfish motives. Even as regards quackery the action of the medical profession was in the interests of the public, for the loss to the profession was as nothing compared to the loss which the public suffered from the robbery of quacks. Death certification again was another instance of the General Medical Council attempting to manage public affairs simply by the intervention of the President. The President of the General Medical Council had had that matter in his hands on behalf of the Council the whole time he (Mr. Horsley) had sat on the Council, and they were not one whit nearer to reform in the matter. If they could bring about reform through the British Medical Association then they would have a ground-work for a real campaign against quackery. He looked upon that as a sort of side wind which would ultimately develop into a powerful gale. He could only conclude as he had begun by thanking them for electing him to the Council.

Dr. E. JERSON proposed a hearty vote of thanks to the gentlemen who had taken the trouble to come so far and speak to them on medico-political matters. He would like to include Dr. A. Cox also in the vote of thanks because he had worked very hard in arranging all the details. For the success of that meeting they were indebted to each one of those gentlemen, especially to those who had come so far—Mr. Jackson from Plymouth, Mr. Brown from London, Dr. Woodcock from Manchester, and Mr. Horsley from London. He wished on behalf of the medical men of the North of England to express gratitude to those who had come and spoken to them.

The vote of thanks was duly seconded and passed with acclamation.

Dr. JERSON having received permission from the meeting to bring forward a motion said that he thought it would be a good way of winding up the proceedings. The motion coincided in a great measure with what had fallen from Dr. Woodcock. The motion was to the effect that the time had arrived when steps should be taken to provide a new Medical Act, to make the General Medical Council more representative of the medical profession, to give greater powers to the Council, to enforce penalties against irregular and unqualified practitioners, and to institute a proper registration of this. He thought it was hardly necessary to point out that greater interest in medical matters had been aroused in the country and it behooved them to stir themselves up as regards reform. In England there were 20,000 medical men directly represented by three members on the Council; in Scotland there were 3000 medical men represented by one; and in Ireland there were 2000 medical men represented by one. If England were represented in proportion they ought to have six. With regard to the universities and corporations the representation for the universities was not in any sort of sense direct—in fact, it was very indirect; and when it was analysed it was found that perhaps half a dozen medical men only had anything to do with the election of a representative for a university on the General Medical Council. They had an instance of that in their own University of Durham. With reference to increasing the powers of the General Medical Council to deal especially with irregular and unqualified practice he pointed out that the properly registered practitioner was now in a more terrible position than a quack because he was well watched and looked after with jealous care, from all of which the quack was free. They should insist upon the proper registration of deaths because it was an important matter and there was greater laxity of the law in regard to it, and inquiry into the death registration would reveal circumstances which would astonish even the most unlearned in the land. He moved that the resolution should be forwarded to the Duke of Devonshire, to the General Medical Council, and to the local Members of Parliament.

Mr. MORISON suggested that the motion should read that the time had arrived when steps should be taken to provide a new Medical Act.

Dr. COX said that if that was the motion he would have much pleasure in seconding it.

Dr. J. F. ARMSTRONG asked what form the Act was going to take. They had had an interesting discussion and many valuable suggestions. But to his mind the motion as just read by Mr. Morison was a crude way of expressing their

wishes. He thought that the motion ought to include the further clauses which Dr. Jepson had suggested. He went into the subject of the registration of deaths in some detail and showed how it was impossible to avoid giving registration certificates without being paid for them and clearly showed that medical men should be paid a fee for certificates of death.

A speaker from the body of the hall moved that the subject should be adjourned. The words "a new Medical Act" were very vague and required considerable discussion. He therefore moved that the subject should be adjourned.

Dr. COX said he thought they were all unanimous that a new Medical Act was necessary and there would be time enough to go into all the details when the subject came before them. He thought that Dr. Jepson's motion as read out by Mr. MORISON was quite in harmony with the views of the meeting.

Mr. MORISON pointed out that the meeting was more representative of the medical profession in that neighbourhood than they would be likely to have for some time. He thought they were all agreed to the motion in the form that he had read it.

Dr. HILL said that if they wanted a new Medical Act they should state what they wanted in it. He would vote against any abstract motion of the kind suggested.

The motion was then put to the meeting by Mr. MORISON and passed with two dissentients.

The proceedings then terminated.

### PLAGUE IN LIVERPOOL.

FIVE or six cases of illness occurred in Liverpool at the end of September and the beginning of October which, while they were set down as influenza, were suspected of being plague. The patients were placed in strict isolation and two of them, two little boys, died. Dr. Bulstrode, medical inspector of the Local Government Board, went down to Liverpool to confer with Dr. E. W. Hope, the medical officer of health upon the situation, and official information has since been received from the Board that the deaths were due to bubonic plague. Dr. Hope submitted on Wednesday afternoon to a joint meeting of representatives of the Health Committee and the Port Sanitary and Hospitals Committee a report containing full information of the circumstances. From the report it would appear that on Oct. 23rd two children named Edward W., aged 12 years, and David W., aged seven years, living at Radcliffe-street, were admitted to hospital as suffering from typhus fever. The ambulance inspectors found on arriving at the house to remove the patients to hospital that one of them, David, was dying, but that another one, James W., was ill. Edward and James were removed to hospital. On Friday evening, Oct. 25th, doubt was raised as to the real nature of the illness of the two children in the hospital, and the medical officer examined the children with Dr. Balfour Stewart. The suspicious character of the illness led to further investigation in the locality whence the patient came, when it was ascertained that a young woman named Margaret K., aged 29 years, residing in Exmouth-street, the house which is in the immediate rear of the W.'s house, was ill. In the meantime reference to the mortality returns had shown that Mrs. K., the mother of this young woman, had died at the same address on Sept. 28th, and that Rosie K., sister of Margaret, had died at the same address on Oct. 3rd, each after a brief illness, one at least of them having, it is alleged, complained of tenderness under the armpits. The deaths in each of these cases were certified to have been due to influenza and disease of the chest. Margaret K. was at once removed to the hospital, the nature of her illness being indicative of plague. On Oct. 18th the death of Mrs. L., in Radcliffe-street, had occurred and had been certified to be due to cerebral apoplexy. This woman was associated with the K.'s and had assisted in the washing and laying out of the body of Mrs. K. Into each of these fatal cases no further investigation was, of course, possible. The illness of both boys, Edward W. and James W., unfortunately had a fatal termination on Oct. 26th and 27th respectively.

These are the two cases in which a bacteriological examination has been made and has served to confirm the diagnosis.

On Oct. 26th two children, Rubina J. and James J., also resident in Exmouth-street, and playmates of the K. family, were found also to be suffering from the plague and were removed to the city hospital, where they are at present, with Margaret K.

Dr. Hope in his report pointed to the fact that the patients were well-to-do people living in a respectable environment, and although one or two cases may still be found it is clear that all possible precautions have been, and are being, taken. From time to time during the past two years cases of plague have arrived in the port of Liverpool—a circumstance which Dr. Hope points out is inevitable in view of the fact that Liverpool trades with every port in the world, whether plague-infected or not. But the country may rest assured that although the door for the possible inlet of plague must always be open at Liverpool the doorkeepers scrutinise the entries so rigorously that anything like widespread infection would be immediately detected and stopped.

### THE FIFTH INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.

HELD AT TURIN, SEPT. 17TH-21ST, 1901.

THE following are some further abstracts of communications made to the above Congress:—

#### *The Vagus Nerve Considered as a Motor Nerve of the Heart.*

Professor ONIMUS (Monaco) brought forward considerations to show that the vagus nerve was like ordinary nerves, one which determined the activity of the organs with which it was in communication. He had found that when excited by a faradaic current interrupted with a frequency approximating the rate of the heart (instead of the usual rapidity of interruption) the nerve did not bring on inhibition of the heart, but, on the contrary, contractions which in the end synchronised with the rate of excitation. In all cases, and in every animal, the frequency of stimulation had much greater influence than the strength of the current, and he believed that it was only because a rapid interruption had ordinarily been employed that the nerve came to be looked upon as inhibitory. For example, to produce arrest it required from 15 to 20 shocks per second in the dog, from 20 to 25 in the rabbit, from eight to 10 in the frog, and from five to six in the tortoise. During the hibernation of cold-blooded animals and in debilitated conditions of the warm-blooded the requisite number was considerably less. Thus after a severe loss of blood in the dog from 14 to eight interruptions per second were sufficient to arrest the heart. It was therefore only under certain conditions that excitation of the vagus brought on inhibition and to understand the why and the wherefore of this it was necessary to regard the nerve as the motive agency of a rhythmic mechanism. A simple illustration would make his meaning clear. Suppose a machine were required to elevate a load one metre high, but that the weight were always caused to drop before reaching that height the machine never accomplished its function, however often and however forcibly the weight might be raised, even to a height of 99 centimetres. In the same way if the duty of a nerve-cell were periodically to call into play the activity of an organ, and if a certain period of rest were necessary after each performance, it could never succeed in fulfilling its function if discharged before the time necessary for the accumulation of the requisite energy. A period of rest, long or short, was essential to all organs, and if too short the machine became exhausted in direct proportion to the using up of the sources of energy accumulated by its nutrition. In voluntary organs such matters were regulated by the will, but in those of involuntary activity, when the period of repose brought the necessary accumulation of energy, function set in spontaneously and rhythmic activity was thus established. But if in these latter activity were provoked before the necessary repair had taken place function could not occur, not because they were paralysed, but because an active status was induced too often. Admitting, for example, that the ganglionic cells of the heart required one second of rest to accumulate the energy for producing a contraction, this latter could never occur if they were discharged every half second or even every three-quarters of a second. The heart would remain in diastole apparently paralysed. The greater case with which the arrest of the heart (abnormal vagus activity)

could be called into play in debilitated conditions also pointed to the same conclusion—viz., that the nerve, like ordinary nerves, was one which called into play the activity of the heart and not its inhibition.

*The Action of Ringer's Fluid and of Dextrose on the Isolated Heart of the Rabbit.*

A very admirable demonstration of the above was given by Dr. F. S. LOCKE (London). An excised rabbit's heart fed solely with Ringer's fluid (through which oxygen under atmospheric pressure had been passed prior to entering the coronary vessels) was kept alive and strongly active for several hours. Ordinarily, weakening set in at the end of two hours, but it was very quickly brought on if the supply of oxygen were cut off. Renewal of the oxygen restored the activity almost as before. When gradual weakening set in under the influence of Ringer's fluid and oxygen the activity could be restored by adding 0.1 per cent. of dextrose to the nutrient fluid. The heart then remained strongly active for at least seven hours as a rule. Removal of the dextrose brought on the weak action at any period, while its renewal restored activity and this could be repeated many times in succession.

*The Influence of Diet on the Restoration of the Asphyxiated Heart.*

Professor PREVOST (Geneva) said that in previous experiments he had found that in attempts to restore the heart of an asphyxiated animal direct massage (with artificial respiration) was insufficient. Fibrillary contractions appeared notwithstanding the massage, and were only obviated by an electric discharge of suitable strength or by sending an alternating current of 240 volts through the organ. Recently Prus had succeeded in the majority of cases in preventing the onset of the fibrillary tremors simply by direct massage with artificial respiration. New experiments were therefore undertaken by Professor Prevost in conjunction with Dr. Batelli. In these it appeared that if the animals had been asphyxiated during digestion, massage without the electric current was often sufficient to restore the heart, but never when the animals were fasting. The effect was most constant after a meal of mixed foodstuffs, and of the individual constituents carbohydrates were the most effective, then proteids, and least of all fats.

*A New Method for Investigating the Effects of Drugs or other Reagents upon the Mammalian Heart.*

Dr. T. G. BRODIE (London) demonstrated an apparatus, devised by him, by which the total work performed by the heart of an animal could be determined before and after the administration of a drug. This was ascertained by recording the total output of the heart made to discharge under a constant pressure into a "stromuhr" which worked automatically. The total work was the product of the output multiplied by the mean pressure. Up till then the influence of anaesthetics had chiefly been studied, from which it appeared that chloroform markedly depressed the working capacity of the organ; ether, on the other hand, had but little effect unless given in very large doses, and ethylene chloride likewise had only a slight influence. Suprarenal extract increased the rate of the beat and largely augmented the work performed. It had, in fact, an antidotal effect to chloroform. If administered before the latter the heart withstood much larger doses of the anaesthetic, while a heart greatly depressed by chloroform recovered completely when suprarenal extract was introduced.

*Demonstration of a Recording Stromuhr.*

Professor HÜRTLE (Breslau) gave a demonstration of a recording stromuhr. The working of the stromuhr was shown on a dog. The volume of the blood passing through it was recorded on a smoked cylinder. Lantern slides illustrating the chief results obtained by it were also exhibited. Amongst others these showed (1) the increased volume of blood flowing through the thyroid arteries after clamping the carotid, distal to their origin; (2) quickening of the blood-stream in one carotid in consequence of compression of the opposite, and also as a result of division of the vago-sympathetic nerve; (3) the blood-stream in the crural artery before and after division of the limb nerves and during tetanic contraction of the limb muscles (the latter caused slowing); and (4) normal blood-stream in the gracilis muscle and also during tetanisation of the muscle. The stromuhr also recorded the pulsatile undulations of the blood-stream, and could thus be used to study the relations between velocity and pressure at different phases of the same pulse curve. On a rapidly

revolving cylinder observations could accurately be made at intervals as short even as one-fifth of a second. These showed that the velocity increased much more rapidly, in proportion, than the blood-pressure, as shown in the following example:—Blood-pressure in millimetres of Hg: 87, 93, 101, 110, 120, 131, 145, 161. Volume of stream in cubic millimetres: 400, 500, 600, 700, 850, 1000, 1200, 1500.

*The Origin of the Lymph in the Peripheral Lymphatic Vessels.*

A contribution to this much debated question was given by Professor G. MOUSSU (Alfort). He had made observations on the peripheral lymphatic circulation of large animals under such varying conditions as muscular rest and activity, physiological activity of all the tissues, during secretion, under variations of blood-pressure both local and general, under the effects of toxins both hypertensive and hypotensive, and under those of ergotin. The following were the chief conclusions at which he had arrived: (1) that the lymph in peripheral districts was not a product of simple transudation from the blood-plasma under the influence of blood-pressure; (2) that this transudation was at all times feeble; (3) that the lymph was above all a product elaborated by the tissues and represented blood-plasma largely deprived of its nutritive constituents; (4) that its formation was in direct correspondence with the vital activity of the tissues; and (5) that the peripheral lymphatic apparatus was in a certain sense an excretory apparatus.

*The Relation of Blood Platelets and Leucocytes to Blood Coagulation.*

Professor G. T. KEMP and Miss H. CALHOUN (Illinois) treated this subject. These workers said that they agreed with those who condemned methods of enumerating the platelets which necessitated the drawing of blood into a melangeur before mixing it with a fixing fluid. Van Emden's recommendation to cool the pipette with ice before using, was less objectionable, but meant considerable trouble. The best method was recommended by Laker in 1886, and independently by Professor Kemp in the same year. This consisted in an enumeration of the red corpuscles by one of the standard methods. They themselves had used the hæmatocrit. The skin of the finger was then pricked through a drop of fluid which fixed the blood platelets immediately. Their number and also that of the red corpuscles were determined in the mixture. The absolute number of the platelets could now be calculated from the ratio they bore to the red corpuscles. The most satisfactory fixative was found to be 2½ per cent. "formol" dissolved in 1 per cent. sodium chloride tinged either with methyl violet or methyl green. The number of leucocytes was determined by the Thoma-Zeiss hæmocytometer, using 1 per cent. acetic acid coloured with methyl violet as the diluent. In normal blood the number of platelets per cubic millimetre taken from a mean of 75 observations on 19 different individuals was found to be 778,000. The maximum was 961,500, the minimum 730,000. In the dog, from 15 observations on 10 different animals, the mean was 381,000, the maximum 461,000, and the minimum 349,000 per cubic millimetre. The ratio to the number of red corpuscles was fairly constant but bore no definite correspondence to that of the leucocytes. The connexion between blood platelets and leucocytes and blood coagulation was investigated by a method which they termed "fractional defibrination." A certain proportion of the estimated blood-content of an animal was drawn, defibrinated, filtered, and returned to the circulation. This process was repeated till fibrin was no longer formed. At each interval the red corpuscles, leucocytes, and blood platelets were counted. A similar method had been used by Bizzozero and Bizzozero with Sanquirico when studying the regeneration of blood and the effects of its transfusion. The platelets disappeared progressively with each defibrination, and after the blood had lost its coagulability (from the sixth to the tenth defibrination) they were no longer present. The leucocytes disappeared to some extent, but never completely. Large numbers of them were, however, filtered out, as shown by examining the same specimen before and after filtration. Mononuclear and polynuclear leucocytes were present at all stages and also after complete defibrination. The red corpuscles suffered some diminution but much less than the leucocytes. In leucæmic blood these changes could be studied very readily. During regeneration the leucocytes returned to their normal numbers first, then the red

corpuscles, and last of all the platelets. Professor Kemp and Miss Calhoun, therefore, disagreed with Lilienfeld that progressive disintegrative changes in the leucocytes accompanied the coagulation of normal blood. Lacerated and broken leucocytes were often to be seen in defibrinated specimens and in films preserved by drying. Any diminution in their number was, therefore, probably due to physical laceration or other such effect rather than to chemical disintegration. A true chemical disintegration was suggested by the fusion and breaking up of the spindle corpuscles of frog's blood, but no similar changes were ever observed by them in mammalian leucocytes. Further, it was the exception for leucocytes to form nodes in the fibrin network of coagulation, while it was the rule for masses of platelets to do so. In diluted blood, however, and in thin films, the fibrin was often deposited as needle-shaped crystalloids totally apart from any of the corpuscular elements. The platelets were biconcave, as Hayem had stated, at least when fixed with osmic acid or examined in Hayem's fluid, but they were never found to contain any traces of hæmoglobin and therefore could not be regarded as hæmatoblasts as Hayem meant. Their micro-chemical reactions resembled those of red corpuscles and also those of the nuclei of leucocytes, but were not identical with either. The platelets resisted the digestive action of dilute HCl and pepsin, as Lilienfeld had shown, and this fact indicated a rich content of nucleoproteid, but Macallum's reaction for phosphorus in organic combination gave discordant results. A definite opinion as to their composition was therefore reserved. Professor Kemp and Miss Calhoun agreed with Bizzozero that the platelets were independent elements since it had not been satisfactorily shown that they were related to, or derived from, any of the better known corpuscular elements of blood. Finally, they were the only elements the disintegration of which was to be seen in the coagulation of normal blood.

#### Recent Researches on Blood.

Dr. A. PETRONE (Naples) related results which he had obtained in the study of blood corpuscles by using dilute sulphuric acid as a fixative. In aqueous solution it was of great value in examining the number of white corpuscles, enabling this to be done with ease, rapidity, and certainty. It also revealed the chief forms of their nuclei and allowed of the staining of their protoplasmic granules beautifully. Altogether it yielded him better results than any other fixative employed. When used in minimal quantities added to absolute alcohol it demonstrated a yellowish-brown iron-holding substance within the red globules which Dr. Petrone claimed to represent the primitive nucleus which had not wholly disappeared. Similar appearances were observed in the nuclei of oviparous and embryonic corpuscles. The alcoholic solution fixed ferruginous substances *in situ* and was thus of special value in studying morbid alterations of the corpuscles in chlorosis, &c. By its employment Dr. Petrone believed that he had contributed to the settlement of two very debated problems in hæmatology—viz., the independence of the blood platelets as claimed by Bizzozero and the persistence of the nuclei of the erythrocytes, which, as stated, were not lost but hidden by a great development of hæmoglobin and at the same time transformed chemically from having acid properties like all other nuclei to being basic in function and reaction. It was essential that the reagents should be pure, and it was hoped that the method, for its own sake, would receive wider recognition.

**SANATORIUM FOR SOMERSET, DORSET, AND DEVON.**—Great interest is being manifested in the proposal for the establishment of a sanatorium for consumptive patients in Somerset, Dorset, and Devon. The subject was recently prominently before the Dorset County Council and the West Hants branch of the British Medical Association.

**READING PATHOLOGICAL SOCIETY.**—The sixtieth annual meeting of the Reading Pathological Society was held at the Royal Berkshire Hospital on Oct. 24th, when Dr. Dawson Williams, the editor of the *British Medical Journal*, gave an oration on "Therapeutic Institutions." The orator reviewed the various institutions which are rapidly appearing in this and other countries for the treatment of special diseases and discussed their effect on medical practice. The members and visitors afterwards dined together.

## Looking Back.

FROM

THE LANCET, SUNDAY, NOV. 2, 1823.

To the Editor of the Lancet.

SIR,—As the instrument you use is calculated to reduce those systems which are overloaded with what the old school would have considered vitiated fluids, I wish to call your attention to a morbid condition of that body to which the public applies the general term of THE FACULTY; in which sweeping appellation is included many beings who have nothing but self-appointed titles, by which they gull the community. We see over the shops, and at the private doors of self-taught druggists, in splendid letters, Surgeon, &c.—Surgeon and Accoucheur, &c. &c.—and, by the effrontery and speciousness of these displays, the multitude believe them worthy of every confidence; and the regular and respectable young practitioner is overlooked and daily insulted through these exhibitions. Now, as there is no redress to be had by an appeal to the legislature, I, as a young though regular surgical graduate and general practitioner, think it would be advisable for those who are in like circumstances to assume some designation which would mark the authority with which we offer our services to the public, and which might be a means of salutary depletion. I would propose that instead of the term surgeon, every member of the college, who deems it right to express the nature of his profession on the front of his dwelling, should write up Collegiate Surgeon. If this suggestion be deemed worthy of consideration, you will oblige me by giving it a place in the Lancet.

I am, yours respectfully,

JUVENIS,

Collegiate Surgeon and Authorised Medical Practitioner.

London, Oct. 24, 1823.

#### NOTICE TO CORRESPONDENTS.

Mr. J. is sincerely thanked for the Copy of Guy's Will; we have not yet had leisure to examine it.

## VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6767 births and 3663 deaths were registered during the week ending Oct. 26th. The annual rate of mortality in these towns, which had been 15.6, 15.9, and 16.8 per 1000 in the three preceding weeks, declined again last week to 16.7 per 1000. In London the death-rate was 16.1 per 1000, while it averaged 17.0 in the 32 large provincial towns. The lowest death-rates in these towns were 9.9 in Wolverhampton, 10.6 in Leicester, 10.8 in Croydon, and 11.4 in Brighton and in Halifax; the highest rates were 21.2 in Plymouth, 22.3 in Manchester, 22.5 in Blackburn, and 25.2 in Newcastle. The 3663 deaths in these towns last week included 398 which were referred to the principal zymotic diseases, against 525, 485, and 467 in the three preceding weeks; of these 398 deaths 114 resulted from diarrhoeal diseases, 80 from measles, 64 from diphtheria, 56 from "fever" (principally enteric), 43 from whooping-cough, 34 from scarlet fever, and 7 from small-pox. The lowest death-rates from these diseases were recorded in Wolverhampton, Leicester, Birkenhead, Burnley, and Gateshead, and the highest rates in West Ham, Cardiff, Norwich, and Blackburn. The greatest mortality from measles occurred in Norwich, Manchester, Blackburn, and Sheffield; from scarlet fever in Blackburn; from whooping-cough in Newcastle; and from diarrhoeal diseases in West Ham, Swansea, Liverpool, Blackburn, and Sunderland. The 64 deaths from diphtheria in the 33 towns included 26 in London, six in Cardiff, six in Leeds, five in West Ham, four in Portsmouth, three in Sheffield, and three in Hull. Six fatal cases of small-pox occurred in London and one in Liverpool, but not one in any other of the 33 towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 169, 175, and 172 at the end of the three preceding weeks, had increased again to 180 on Saturday, Oct. 26th; 57

new cases were admitted during the week, against 51, 37, and 47 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 3353, against numbers increasing from 2994 to 3344 on the seven preceding Saturdays; 400 new cases were admitted during the week, against 426, 422, and 407 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 132, 186, and 196 in the three preceding weeks, further rose last week to 242, but were 73 below the corrected average number. The causes of 33, or 0.9 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Leeds, Hull, and in 16 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Sheffield, and Newcastle.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 14.5, 16.1, and 16.9 per 1000 in the three preceding weeks, further rose to 19.3 per 1000 during the week ending Oct. 26th, and was 2.6 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13.7 in Paisley and 14.7 in Leith to 23.6 in Aberdeen and 29.0 in Greenock. The 616 deaths in these towns included 27 which were referred to diarrhoea, 13 to "fever," 12 to measles, eight to whooping-cough, five to diphtheria, and four to scarlet fever. In all, 69 deaths resulted from these principal zymotic diseases last week, against 62 and 79 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2.2 per 1000, which was 0.4 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhoea, which had declined from 53 to 30 in the five preceding weeks, further decreased last week to 27, of which 12 occurred in Glasgow, seven in Aberdeen, three in Edinburgh, two in Leith, and two in Greenock. The deaths referred to different forms of "fever," which had been six, six, and five in the three preceding weeks, rose again to 13 last week, and included 11 in Glasgow. The fatal cases of measles, which had been 14, six, and 15 in the three preceding weeks, declined again last week to 12, of which 10 were registered in Glasgow and two in Dundee. The deaths from whooping-cough, which had been five and 12 in the two preceding weeks, declined to eight last week, and included six in Glasgow and two in Edinburgh. The fatal cases of diphtheria, which had been six, six, and 12 in the three preceding weeks, declined again last week to five, of which three occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 75 and 97 in the two preceding weeks, further rose last week to 133, but were six below the number in the corresponding period of last year. The causes of 23, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19.9, 19.7, and 19.9 per 1000 in the three preceding weeks, declined again to 19.3 per 1000 during the week ending Oct. 26th. During the past four weeks the death-rate has averaged 19.7 per 1000, the rates during the same period being 15.5 in London and 15.4 in Edinburgh. The 139 deaths of persons belonging to Dublin registered during the week under notice showed a decline of four from the number in the preceding week, and included nine which were referred to the principal zymotic diseases, against 20, 21, and 10 in the three preceding weeks; of these, five resulted from diarrhoeal diseases, two from whooping-cough, one from scarlet fever, and one from diphtheria. These nine deaths were equal to an annual rate of 1.3 per 1000, the zymotic death-rate during the same period being 1.4 in London and 1.5 in Edinburgh. The deaths from diarrhoeal diseases, which had been nine, 14, and five in the three preceding weeks, were again five last week. The mortality from whooping-cough was slightly in excess of that recorded in each of the two preceding weeks. The 139 deaths in Dublin last week included 28 of children under one year of age and 33 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a considerable

diminution as compared with the numbers in the preceding week. Five inquest cases and three deaths from violence were registered; and 46, or about one-third, of the deaths occurred in public institutions. The causes of six, or more than 4 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeon A. Patterson to the *President* for three months' hospital study. Surgeons: A. La T. Darley and E. S. Tuck to the *Duke of Wellington*; O. Rees to the Cape Hospital; W. J. Coddington to the *Gibraltar*; and H. Spicer to the *St. George*.

### ROYAL ARMY MEDICAL CORPS.

Captain John Thurlow Olapham is placed on temporary half-pay on account of ill-health. Dated Oct. 21st, 1901. Lieutenant-Colonel George Harrison Younge retires on retired pay on account of ill-health. Dated Oct. 30th, 1901. Captain F. J. W. Porter is seconded for service with the South African Constabulary. Dated July 1st, 1901.

It has been decided that civil surgeons who have been appointed to the Royal Army Medical Corps, may count their service in South Africa towards retirement, but not towards promotion.

Lieutenant-Colonel H. J. Barnes has arrived at Colchester for duty and has assumed medical charge of officers, women, and children.

Out of the probable prospective increase of 102 officers to the corps 40 will be added to the cadre in India.

### INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the following promotions among the officers of the Indian Medical Service:—Lieutenants to be Captains (dated July 27th, 1901): Thomas Hunter, Walter Rothney Battye, Harold Budgett Meakin, George Hutcheson, William Glen Liston, Harold Boulton, Richard William Anthony, Ernest Frederick Gordon Tucker, George Edward Stewart, Frank Stuart Corbitt Thomson, Thomas Shepherd Novis, John William Watson, and Herbert Joseph Richard Twigg.

The King has also approved of the retirement from the service of Lieutenant-Colonel Sarkies Thaddeus Aveloon (Bombay Establishment). Dated Oct. 1st, 1901.

### VOLUNTEER CORPS.

*Rifle*: 4th Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Lieutenant F. Norman to be Surgeon-Captain. 2nd Volunteer Battalion the King's (Liverpool Regiment): John Graham Martin to be Surgeon-Lieutenant.

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Albert Hilton, 3rd Volunteer Battalion the Manchester Regiment, to be Surgeon-Lieutenant.

### SOUTH AFRICAN AFFAIRS.

There has been a good deal of fierce fighting on a relatively small scale near Zeerust, when the British were attacked by Delarey and Kemp's commandos; the casualties on both sides were severe. Several engagements have also taken place in various directions elsewhere, otherwise there is not much military news of any importance to be chronicled. What there is, if taken as a whole, is distinctly favourable, although it is not of a decisive character and does not point to any speedy end of the struggle in South Africa.

The system adopted by Lord Kitchener seems to be, practically speaking, the only available one under the circumstances. Under that system the detachments of troops scattered throughout the various districts and along the line of rail occupy blockhouses of corrugated iron surrounded by barbed wire. These form excellent defensive posts, while columns making concerted and converging movements are free to operate elsewhere and to sweep the country and make attacks from time to time on the Boer laagers. If the process is slow it is nevertheless sure, and from all we hear systematic progress is being made—the Boer raiders in the Cape Colony are being steadily driven back, laagers are from time to time surprised and Boers captured, together with the loss on their part of munitions of war, transports, cattle, and supplies. There have been rumours of the death of De Wet, but we shall probably find ere long that that redoubtable and

enterprising warrior is still very much alive and that he has simply been hibernating while hatching some new scheme during his retirement from active operations in the field. Previous experience has shown that irregular warfare of this kind is almost always protracted. It was so in Bosnia and in the Burmese war, and it is so, as the Americans find to their cost, in the Philippines, whither large reinforcements will have to be sent from the United States.

From all that we can learn—and some of our information is gathered from private letters received from those on the spot—there is a very large amount of exaggeration about the condition of the Boer women and children in the camps of concentration. They are well supplied and well cared for. What is wanted is sanitation and a change of site for these camps and the splitting of them up into smaller camps, but this entails great difficulties of administration and not least so in finding a sufficient number of medical officers for the purpose. It is the aggregation, however, of too many people on limited and fouled sites, offering such facilities for the breeding and spread of infection, and the want of proper care and personal cleanliness on the part of the Boers, that have been the main causes of the sickness and mortality among them.

The list of casualties has, of course, increased since we last wrote owing to recent fighting and there is still a very regrettable amount of sickness (mostly from enteric fever) present. We hope that all practicable precautions are being taken for the coming hot season in South Africa.

#### THE SOUTH AFRICAN CONSTABULARY.

Lady Baden-Powell has issued a circular letter to the press in which she expresses on behalf of herself and those associated with her grateful thanks to the many anonymous donors who are sending parcels and money to buy Christmas comforts for General Baden-Powell's South African Constabulary. She also wishes it to be known that the committee have received as many books and magazines as can be forwarded, and that it would greatly facilitate the work of distribution if those who prefer to send in their own parcels would put "S.A.C." and their names clearly on the outside of each parcel. At the same time contributions in money are preferable, affording a great economy in packing and transport. Tobacco can be sent out "in bond" and in special air-tight cases. Funds can be sent to any of the following ladies, and will be personally acknowledged by General Baden-Powell; Lady Baden-Powell, 114, Eaton-square, S.W.; Mrs. Nicholson (no parcels), Basing Park, Alton, Hants; Mrs. McLaren, Glengarry, Woking; and Miss Baden-Powell, 8, St. George's-place, Hyde-park-corner.

#### SYRACUSA CONVALESCENT HOME, TORQUAY.

The half-yearly meeting of the subscribers of this convalescent home for wounded soldiers from South Africa was held on Oct. 22nd. The report showed that during the 21 months the home had been opened 256 men had been admitted, the stay on an average being two months, and the cost for food about 8s. weekly. The subscriptions during the time had amounted to £3042 and there was a favourable balance of £794. The sub-committee have decided to close the home in December next, when it will have completed two years' useful work, and as the Government have now plenty of accommodation at their disposal for convalescent soldiers it is considered that there is no necessity for keeping the home open after the end of the year.

#### LEAN'S ROYAL NAVY LIST.

Few works of reference are so accurate in detail or are arranged in such an admirable manner for ready reference as Lean's Royal Navy List. The ninety-sixth issue of this quarterly publication is now before us and contains matter of interest to all whose business or calling brings them in contact with the King's Navy. Promotions, retirements, and appointments as recent as Nov. 1st are recorded. The publishers are Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's Court, Cornhill. The price of a single volume is 7s. 6d.; the yearly subscription is £1 7s. 6d.

**A CENTENARIAN.**—It is stated that Signor Angelo Alviti, a lawyer at Alatri in Italy who is 101 years of age, has just married a woman of the age of 26 years. Signor Alviti's mother was said to have died at the age of 105 years. He has two daughters aged respectively 77 and 72 years.

### THE REORGANISATION OF THE ARMY MEDICAL SERVICES.

To the Editors of THE LANCET.

SIRS,—The report of Mr. Brodrick's Committee on the Reorganisation of the Army Medical Services has called forth a great amount of criticism. Much of this criticism is appreciative and generous, and much of it that is hostile is full of valuable suggestions for amendment. Among those, however, who condemn the scheme with such a thoroughness as marked the cursing of the jackdaw of Rheims are some who have evidently imbibed the principle that the Army Medical Service can do nothing but evil all the days of its life, and must, even in its attempts at reform, be influenced by a kind of original sin. There are others who condemn the report *in toto* because they disapprove of certain matters of detail contained therein or base their condemnation upon the omission of details with which the committee could have in a general report no possible concern. There has, indeed, been a disposition in many quarters to appraise the scheme upon a consideration of isolated particulars which, although important in themselves, are insignificant when compared with the general principles upon which the plan suggested in the report is founded. These general principles have been by many critics totally disregarded and have been by others made subservient to matters of secondary import. I should be glad to be allowed to draw attention to the main bases upon which the scheme is founded, lest they be lost sight of in the numerous side issues which are being raised.

In the first place, it may be pointed out that the subject is a very vast one and that the report provides no more than a framework upon which it is hoped that a system of reconstruction may be based. It has no pretence to be a scheme complete in all details. I think that my civilian colleagues on the committee will agree with me that the attitude of the Secretary of State for War in presenting the scheme was not that of a Minister granting concessions under pressure, but that of a Minister who was earnestly desirous of establishing an Army Medical Service which should attract candidates of the best type, which should offer them every inducement to remain in the service, and at the same time to make advance in the work of their profession and fit themselves for the increasing responsibilities of their office. Above all was the desire that the medical department should be made absolutely efficient, should be made worthy of the great army with which it is associated, and should aim at becoming the best medical service of which any country could boast.

The principal features of the scheme are as follows:—

1. The Royal Army Medical Corps is to be under the supervision of an Advisory or Consulting Board, composed of six army officers and four civilians. The Director-General, however, remains "responsible for the administration of the army medical services" and is "responsible for the distribution, promotion, discipline, and general organisation of these services."

2. A very substantial increase in the *personnel* of the Royal Army Medical Corps is rendered necessary.

3. The pay is increased and is raised to a standard more in accord with the pecuniary prospects of a medical man in civil practice at the present time.

4. Liberal opportunities for study are given, while the increase in the corps will obviously give each officer a less share of foreign service.

5. Advancement in the service is by professional merit in distinction to the plan of advancement by seniority. The most speedy promotion falls to the best medical officer.

6. Charge pay is granted and an increased rate of pay is given to those officers who qualify and are employed in certain special branches of medicine and surgery.

7. The establishment of a military hospital and medical staff college for the training of officers of the Royal Army Medical Corps is strongly urged.

The most vigorous objections to the plan laid down in the report are directed to three matters: 1. The Advisory Board. 2. The system of examinations. 3. Certain questions of pay.

1. The utility of the Advisory Board has called forth great diversity of opinion. Those who think the institution of such a board most admirable are equal in numbers to those who condemn it absolutely. Considering the very wide range of subjects which must come within the purview of those who are responsible for the administration of the medical services of the army it would seem that an Advisory Board is almost a necessity. It is an Advisory Board and not an Executive Board. The executive rests with the Director-General. There is nothing in the report to justify the comment of one critic that under the new scheme "the Director-General as a personal factor in the R.A.M.C. practically disappears," nor is there any basis for the suggestion that the board is the outcome of a mistrust in the executive. It would not be difficult to show that an Advisory Board, such as is suggested, would greatly strengthen the hands of those who are charged with the varied responsibilities of administration. Those who condemn the board under the impression that promotions are made by it should read paragraphs 14, 18, and 19 of the report in which it is clearly laid down that the Director-General is "responsible for promotion."

2. The system of examinations has led to much adverse comment. It is the purpose of these examinations to make promotion in the service dependent upon professional ability and to grant the fullest advantages to the officer who does his best to keep his medical and surgical knowledge abreast of the times and who has taken the pains to master some speciality in practice. After receiving his commission an officer under the new scheme undergoes three examinations in the place of two which formerly existed, one of which has sunk into abeyance. So great an alteration has been made in the entrance examination that it has ceased to be the vexatious and irritating test that it was. All the examinations are intended to be practical and as far as possible by *vivâ voce*. The system of testing proficiency by examination is—and always has been—open to considerable question. This applies not only to these particular tests but to all medical examinations. The powers that be, however, have not yet devised any method other than that of examination whereby the entrance of a candidate into the profession can be determined or his fitness for the higher degrees decided. In many hospitals the selection even of house surgeons is by examination. Indeed, at present no other means presents itself which could be regarded as just and adequate except the testing by examination, and it is noteworthy that those who object to such testing in the case of the Army Medical Service have suggested no substitute measure. No one has recommended that promotion should depend upon "confidential reports," and I imagine that no one could be found who would defend that unjust and objectionable system. It must be remembered that while mere promotion is by an examination which tests the officer's capabilities as a professional man, the selection of officers for special appointments rests with the Director-General who will no doubt be influenced by evidence of special fitness in those eligible for such appointments. The examination which has excited most comment is that for promotion to the rank of lieutenant-colonel. This must be passed before the officer has completed 20 years' service and as a preparation for it a period of three months' study is granted. The examination does not deal with medicine or surgery or with any allied science. It is concerned solely with the very administrative work which the officer will—if promoted—be called upon to carry out. Among the subjects are the following: "Hospital organisation, administration, and equipment in peace and war," "The sanitation of towns, camps, troop transports, &c.," "Epidemiology and the management of epidemics," and "The duties of all ranks in the Royal Army Medical Corps." (It is probable that no great stress would be placed upon two of the subjects—viz.: "The medical history of important campaigns" and "The army medical services of other Powers.") The candidate is required to obtain 50 per cent. of the total number of marks. If he fails he is allowed to present himself for a second examination at the end of six months. If he again fails to obtain 50 per cent. of marks he is "compulsorily retired on a gratuity of £2500, or he may, by special permission of the Secretary of State, complete 20 years' service and then retire on a pension." While every possible consideration should be shown to any officer who has been in the service for nearly 20 years it can scarcely be considered a hardship if before he is raised to a position involving very responsible duties he should be asked to give evidence of a minimal knowledge of the matters appertaining to those duties. Moreover, should

it become evident, after two trials, that he does *not* possess that knowledge it would hardly be right to promote him to a post in the qualifications for which he has shown himself hopelessly lacking. No man competent to undertake the duties of the higher rank could object to the examination. The incompetent man naturally would object to it.

3. On the subject of pay I am not competent to speak. I would only say that from a comparison of the proposed rate with that now in vogue it would appear that the increase is substantial and generous. It is possible that the scale will need amendment in certain directions, and it is possible also that the much-cherished "right" to retire after 20 years' service on £1 a day has not been so entirely overlooked as some who have written on this subject suppose.

I am, Sirs, yours faithfully,

Wimpole-street, London, W. FREDERICK TREVE.

#### To the Editors of THE LANCET.

SIRS,—“I am the commanding officer,” was the reply of the chief medical man on board an American hospital ship, which with regard to equipment and management is described as “approaching perfection,” when he was asked where the captain was. If our Army Medical Service is to approach perfection the chief surgeon with an army in the field must in like manner be his own commander, subject only to the general. At present the chief surgeon is expected to serve many masters, and the highest authority has pronounced that to be impossible. Until the chief surgeon is delivered from the power, amongst others, of the commissariat and ordnance departments he never will be able to do justice to the sick and wounded during a campaign. Transport and equipment should be under his control. This means money, and a great deal of it, and it is imperative that the people of England should know how the matter stands. If they choose to find the money well and good, but it is unfair to blame the surgeons for failing to do impossibilities.

I am, Sirs, yours faithfully,

Oct. 28th, 1901. PROPHYLAXIS.

### ARSENIC IN BEER: THE EPIDEMIC OF PERIPHERAL NEURITIS.

#### To the Editors of THE LANCET.

SIRS,—In answer to your kind request that we should state the facts of our position with regard to the recent epidemic of peripheral neuritis we take pleasure in sending the following particulars:—

In September of last year we noticed the excessive incidence of peripheral neuritis in patients attended both in and from the Chester Infirmary, and quite independently concluded that many of the cases more closely resembled beri-beri than any other disease of which we were cognisant. Knowing of the recent epidemic at the Richmond Asylum, Dublin, we communicated with Mr. Conolly Norman, who very kindly, on Nov. 12th, sent us his notes on the subject. A perusal of these strengthened our opinions, and on Nov. 17th we completed a paper which appeared in the *British Medical Journal* of Dec. 1st. On Nov. 23rd we learnt with some surprise of a similar epidemic in Manchester, and on the evening of that day one of us (J. R. P.) went over, and, through the courtesy of Dr. Corsar Sturrock, was allowed to see several of the cases in the Manchester Royal Infirmary and was able to demonstrate the presence of a peculiar pre-tibial and pre-sternal œdema in each case, a point which had up to then escaped observation there. On the morning of Nov. 24th we called upon the medical officer of health of Chester, and with him saw the chairman of the Public Health Committee, and with a view to eliminating our theory of the disease we urged that an expert in tropical diseases should be asked to see the cases at once. Accordingly on the next day Major Ronald Ross came over, and by the kind permission of the medical staff saw 10 of the home and in-patients of the Chester Infirmary, and expressed his opinion that the disease resembled tropical beri-beri even to the minutest details. Major Ross forwarded a communication to that effect which appeared in THE LANCET of Dec. 8th, p. 1677. With regard to the etiology of the disease we cannot do better than refer you to our conclusions which appeared in the *British Medical Journal* of Dec. 8th. Our main contention was the extreme resemblance which the cases presented to beri-beri, and we expressed the opinion that they were either this disease or

that a condition indistinguishable from it could be produced by some other cause. These ideas were very adversely and, we think, unfairly criticised, and now, after the lapse of nearly a year, appear to be receiving considerable confirmation.—We are, Sirs, yours faithfully,

W. A. NEWALL, M.D., Ch. B. Vict.

J. R. PRYTHERCH, M.B., Ch. B. Edin., M.R.C.S. Eng.,

## THE NEEDS OF THE ROYAL LONDON OPHTHALMIC HOSPITAL (MOORFIELDS).

*To the Editors of THE LANCET.*

SIRS,—A year has now passed since the governors of the Royal London Ophthalmic Hospital were summoned for rates. At that time, thanks to the publicity given to the case, both by the London and by the provincial press, many friends sent prompt and generous help enabling the committee to meet this demand, and the rates were fully paid. The committee, have now, however, to face a similar demand, and this at a time when they are seriously hampered in their endeavours to meet the ordinary expenses of the hospital, by reason of the calls on the charitable public of other and more national demands. We, therefore, beg you to help them by making known to the public the very grave position of this great charity.

The committee had hoped that during the last session of Parliament an Act would have been passed to relieve hospitals, wholly or in part, from rates, but, although the Select Committee appointed by the House of Commons made their report as far back as July, 1900, there has been up to the present no legislation on the subject. The report called attention to the numerous anomalies existing in the rating of hospitals, some of which are exempted from rates by local statutes, while many have been treated with the greatest consideration by the rating authorities. On the other hand, the rates are a heavy burden to some hospitals, but few are so terribly crippled by them as the Royal London Ophthalmic Hospital, which is still compelled to keep half its beds closed, and although last year the annual subscriptions amounted to £1096, out of these rates and taxes to the extent of £896 had to be paid. This year the hospital has already paid £700 on this account, and now a further demand is made for £250. The local rating authorities say they cannot lower the assessment, and point out as one reason that this great hospital does not exist for the relief of the district or even of the City alone, but receives patients from every part of the kingdom. Therefore, the committee appeal to all for help to enable this national charity to tide over a pressing emergency.

Donations and annual subscriptions may be paid to Williams Deacon's Bank Limited, 20, Birchin-lane, E.C., or to the Secretary at the Hospital.

We are, Sirs, yours faithfully,

AVEBURY,

President,

H. P. STURGIS,

Chairman of the Committee of Management,

HY. DAVISON,

Chairman of the Finance Committee.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital),  
City-road, E.C., Oct. 28th, 1901.

## "ACUTE DILATATION OF THE STOMACH"

*To the Editors of THE LANCET.*

SIRS,—The following remarks may be of interest in connexion with the paper on Acute Dilatation of the Stomach, with Illustrative Cases, read before the Royal Medical and Chirurgical Society on Oct. 2nd by Dr. H. Campbell Thomson, THE LANCET.<sup>1</sup> Acute gaseous dilatation is of frequent occurrence, often associated with agonising pain and with a feeling of impending death, yet not fatal. In cases of this sort there is no permanent obstruction; usually unaccompanied by vomiting they tend to be relieved by it when it does occur. In them the pain is due to the excessive pressure of gastric inflation superadded to the normal or to an increased volume of intestinal gas, and the abdomen is

enlarged, but to a great extent into the thorax. Fatal cases such as are brought forward by Dr. Thomson differ from them in all those particulars. The pain is not acute, vomiting does not relieve, the abdominal distension is not necessarily considerable or may be almost absent, the gastric distension makes for the abdomen rather than for the thorax, and the intestine is almost airless. Death occurs from the exhaustion of vomiting rather than from pressure. These are essentially cases of obstruction.

As noted by Dr. Thomson, the dilated stomach is bent at an angle, and, as I have repeatedly demonstrated in the post-mortem room, not only the pyloric portion, but the first part of the duodenum, is apt to take a sharply ascending direction, and the pancreas is also made to slope. The mechanism of the distension is obscure, and although in both groups we may admit a large element of disturbed innervation we are still unable to determine where the gas or the fluid may come from. But the mechanism of the fatal obstruction is capable of explanation and sometimes of relief, at least in a section of the cases. That in these the pylorus is not the seat of absolute obstruction is almost proved by the circumstance, urged by Dr. Voelcker in the discussion on the paper, that bile is vomited: it is entirely proved, as in Dr. Thomson's Case No. 2, by the fact that the first portion of the duodenum is distended as well as the stomach. As to Dr. Thomson's other cases, it may perhaps be allowable to suppose, in the absence of any statement to the contrary and on the strength of definite observations made in other instances, that in them the duodenum may have been in an analogous condition. Collateral evidence of the absence of pyloric stricture is afforded by the 10 cases which he tabulates,<sup>2</sup> only one of which presented pyloric disease (described as "narrowing the orifice"), whilst in the remainder no abdominal lesion was found except in two cases where the disease was in the vicinity of the duodenum. The combination of a collapsed intestine and of a distended first part of the duodenum, as in Dr. Thomson's Case No. 2, sufficiently localises the obstruction. The latter is found, as was shown by Rokitsky, and later by Glénard, Kundrat, Schnitzler, Albrecht, and others, at the junction of the jejunum with the transverse portion of the duodenum; this is strangled by the weight of the collapsed intestine which drags the mesentery, and particularly the superior mesenteric artery, as a cord over it. According to this view the collapse of the intestine, however produced, whether from marasmus or more often from shock or exhaustion, is the primary event and not the result of compression by a dilated stomach, and obstructive gastric distension follows. As mentioned by P. A. Albrecht, whose exhaustive essay in Virchow's Archiv<sup>3</sup> was referred to in a joint communication made by Mr. F. Jaffrey and myself to the Harveian Society of London<sup>4</sup> "on a case of uncontrollable vomiting relieved by laparotomy and manipulation, and due to the pressure of an aneurysm," the individual length of the mesentery is one of the etiological factors. Intestinal collapse further elongates it so as to allow the intestine, particularly in women, to drop like a dead weight permanently into the pelvis. It is unnecessary that I should dwell upon the other factors and upon the various views which have been advanced, having given a brief account of them in the remarks appended to the paper just mentioned.

This anatomical explanation is probably applicable, with variations, to most cases, and in particular to those which occur after operations involving profound anaesthesia and shock, and to those which arise apparently spontaneously after relatively trivial complications, where the subjects are predisposed to enteroptosis by the original length of their mesentery and by previous malnutrition and exhaustion. I have suggested that in some of the mysterious cases of so-called "hysterical or neurotic" type, with advanced emaciation and prostration, the persistent vomiting may be kept up by analogous conditions independently of any major gastric dilatation.

The treatment of this form of obstruction is suggested by its cause. The stretched mesentery must be relieved by raising the intestine from the pelvic trough. The rational cure for the visceral malposition and the resulting gastric dilatation is posture. The knee and elbow position advocated by Albrecht may not often be available owing to

<sup>1</sup> Loc. cit., p. 1115.

<sup>3</sup> THE LANCET, Oct. 28th, 1899, p. 1155.

<sup>1</sup> THE LANCET, Oct. 26th, 1901, p. 1113.

<sup>2</sup> Loc. cit., p. 1122.

the patient's weakness, but it may be possible to incline the patient to the right, to elevate the pelvis on pillows, and to raise the foot of the bed, whilst skilled manipulation is applied to the abdomen by the medical attendant himself. These simple measures should be borne in mind in all cases of persistent vomiting supervening in emaciated and exhausted subjects. Lavage is an obvious indication; and if, as alleged by L. Meyer, a distended and depressed stomach is competent to obstruct the duodenum, it might sometimes prove an effectual remedy. If all this should fail laparotomy remains as the only resource, and it should be performed with an eye to the form of obstruction to which I call renewed attention, and which, to include all varieties, might be described as "duodenal pressure-obstruction."

I am, Sirs, yours faithfully,

WILLIAM EWART, M.D. Cantab., F.R.C.P. Lond.,  
Senior Physician to St. George's Hospital and to the  
Belgrave Hospital for Children.  
Curzon-street, W.

*To the Editors of THE LANCET.*

SIRS,—Curiously enough, before I had seen Dr. H. Campbell Thomson's paper upon Acute Dilatation of the Stomach in THE LANCET of Oct. 26th, p. 1113, a case met with in the post-mortem room this afternoon seemed to suggest that probably many of the cases of moderate dilatation of the stomach found after death are of acute nature. In a woman, aged 25 years, who had died from puerperal fever, the stomach extended below the umbilicus, and, although it contained only about eight ounces of fluid it was found to be capable of holding 150 ounces of water without further distension. The duodenum also was much distended and was fully double its normal size. The jejunum was unaffected. In the last number of the *Bristol Medical-Chirurgical Journal* is a reproduction of a rough sketch of mine of a dilated stomach, which must almost, if not quite, have equalled in size the stomach of which Dr. Thomson has given an illustration. No mechanical obstruction was pre-ent and the duodenum in this case also was much distended. The cause of death was septicæmia associated with a suppurating thrombus in the left cavernous sinus.

I am, Sirs, yours faithfully,

Clifton, Bristol, Oct. 26th, 1901. THEODORE FISHER.

*To the Editors of THE LANCET.*

SIRS,—I shall be much obliged if you will allow me to add a few additional references to my paper on the above subject which appeared in THE LANCET of Oct. 26th, p. 1113. Since my paper was written I have had an opportunity of seeing the recently published work on "Diseases of the Stomach and their Surgical Treatment" by Mr. Mayo Robson and Mr. Moynihan. In the chapter on Acute Dilatation four fatal cases are recorded as having occurred at the Leeds Infirmary and two others in which recovery took place after the onset of acute symptoms; other cases in English and foreign literature are also alluded to. Among other interesting communications on this subject are those of C. R. Box and Outhbert Wallace,<sup>1</sup> Dyson,<sup>2</sup> Kelynack,<sup>3</sup> and Donald Hood.<sup>4</sup>

I am, Sirs, yours faithfully,

H. CAMPBELL THOMSON.  
Queen Anne-street, W., Oct. 28th, 1901.

"THE AFTER-COMING HEAD; PREVENTION OF ASPHYXIA."

*To the Editors of THE LANCET.*

SIRS,—In reply to Dr. Edwin Smith's letter in THE LANCET of Oct. 26th (p. 1155) in which he asks what are the objections to the introduction of a tube into the child's mouth in cases of delay of the birth of the after-coming head, does it sometimes fail, and, if so, why? I would give the following answer. 1. The difficulty of introducing such a tube and keeping it *in situ* may be considerable. 2. Even after its introduction it is often impossible to get the child to breathe with its head in the vagina. 3. In many of these cases, owing to premature efforts at respiration having been made, the child's mouth and pharynx contain foreign matters, such as liquor amnii

and blood. 4. Under these conditions the introduction of a tube, especially if the child be further stimulated to breathe, is likely to favour the passage of such fluids into the larynx and so further to increase the risk to the child's life. 5. The time spent in introducing a tube would be better employed in applying forceps to the head since cases are very rarely met with in which the head cannot be at once delivered by the use of forceps. 6. If the child makes attempts at respiration with the head still in the vagina, the immediate delivery of the head and the performance, if necessary, of artificial respiration are likely in the majority of cases to give better results than the use of a tube. 7. If the use of the tube fails, as the recorded cases show it sometimes does, valuable time will have been lost. 8. As the child's life is in danger any risk to the perineum of the mother may be neglected. I am quite prepared to admit that a delay of a few minutes may make all the difference to the chances of a bad tear of the perineum, but, as I have already said, when the life of the child is at stake this risk should not be taken into consideration. It is probable that the best results will be obtained in these cases by having ready at hand all the appliances necessary to revive the child if it be born asphyxiated; by keeping up well-applied pressure on the fundus of the uterus during the delivery of the trunk, so as to avoid extension of the arms and head; and by delivering the head as rapidly as possible if the child's life is endangered by shoulder and jaw traction, or, better still, by the application of forceps.

I am, Sirs, yours faithfully,

Wimpole-street, W., Oct. 29th. GEORGE F. BLACKER.

"THE SANITARY STATE OF TORQUAY."

*To the Editors of THE LANCET.*

SIRS,—I was glad to see in THE LANCET of Oct. 19th, p. 1075, a letter requesting you to use influence with the town council of Torquay to remove the Destructor from its present position. The letter fully explained why the situation in which it is placed is incurably faulty. But it hardly mentioned that the Destructor Committee hardly deny that the fumes issuing from the chimney are injurious to health, and intend—let me quote from the local paper—"to engage an analytical chemist of the first rank to analyse the fumes as they emanate from the destructor furnace" in order that the said wise-heads may determine whether "the complaints are founded on fact or fancy" and whether "the fumes are or are not noxious." As if fumes could be anything but noxious. So much for the judgment of our sanitary authorities. *Quis custodiet, &c.* Of course there are mortals whose noses are only more or less ornamental appendages, but even they condemn the clouds of smoke which drift round and about.

Our *patres conscripti* are not satisfied with this outrage on the purity of our air. A charming valley that, if at Bournemouth, would have been lovingly planted with flowers, is being, "by authority," filled with the garbage of the town. From this baleful barbarism issue breezy odours hardly helpful to those with delicate lungs, or throat, or stomach. We Uptonians are poor and cannot afford to apply for a legal injunction, and therefore we appeal to an authority respected by the civilised world—to you, Sirs—to aid us in the abolition of these nuisances.

I am, Sirs, yours faithfully,

S. GROSE, M.D. St. And., F.R.C.S. Eng.  
Torquay, Oct. 25th, 1901.

"THE TREATMENT OF TUBERCULOSIS."

*To the Editors of THE LANCET.*

SIRS,—You published a few years ago a case of mine, "A Child, Four Years Old, with Acute Phthisis. Cured."<sup>1</sup> I then detailed the treatment. In all the correspondence I have seen in THE LANCET on tuberculosis nowhere have I seen any medicinal treatment recommended as having proved successful where everything has been against the patient's recovery, but as hundreds of cases of phthisis occur in which the patients are pecuniarily unable to avail themselves of the open-air treatment, it remains that such patients must die unless by medicinal treatment something can be done to check the disease if not to destroy it.

<sup>1</sup> Transactions of the Clinical Society of London, 1898.

<sup>2</sup> Medical Press and Circular, vol. i., 1897.

<sup>3</sup> Medical Chronicle, vol. xvi., 1892.

<sup>4</sup> THE LANCET, Dec. 19th, 1891, p. 1389.

<sup>1</sup> THE LANCET, June 4th, 1898, p. 1536.

For years I have tried the treatment which proved successful in the case published and now I have three cases which may be seen. One is the case of a very near relative, a young man, aged 21 years. His illness began with an attack of influenza. He was a clerk away from home a day's journey, persisted in going to his work, slept in a bed in which the late occupant (the landlady's husband) died from phthisis, and of which he was not even made aware till after pulmonary tuberculosis plainly manifested itself, when the landlady informed him that "he was just like her late dear husband who died on that very bed he had been sleeping on." Means were not available to send this young man away. He has been treated at home, yet in spite of a decided check caused by a chill caught through carelessness by lying on the grass, setting up pneumonia with pleurisy, he is gaining strength, sweating has ceased, and he is gaining weight rather than losing. I feel this case so far will be enough and I need not trespass on your space with others to show that medicinal treatment, apparently neglected, may do much to alleviate the distress and the loss sustained by this disease.

I am, Sirs, yours faithfully,  
G. P.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

### *The Plague Epidemics.—Collapse of the Outbreak of "Epidemic Dropsy."*

ANOTHER slight receding wave is noticeable in the general movement of plague mortality in India. This week there have been 236 fewer deaths, the total being 7043 as against 7279 last week. The reduction has taken place in the Bombay Presidency. A slight increase has occurred in the Punjab and Mysore. Bombay City returns 182 deaths, the Punjab 164, and Mysore State 345. Plague has appeared suddenly in Benares, but only a few cases have occurred as yet. The usual experience seems to be that when the disease either first attacks a place or recurs in it cases keep cropping up in small, but perhaps gradually increasing, numbers for several weeks, and that it then seems to take on a sudden outburst and rapidly develops to its maximum. After the maintenance of a very high mortality for a short time it subsides as rapidly as it rose. There are at the present moment several places in India where the disease has commenced to develop or to recur during the past few weeks. There are others where the disease continues mildly but uninterruptedly. The latter may expect their outbreaks in due course—that is, when the usual intervals have elapsed. As plague outbreaks have occurred at all seasons of the year the determining cause would seem to be independent of heat, dryness, or altitude. For any given place the accident of introduction would seem to determine the time of the year when it should be subjected to the epidemic influence. No other explanation seems satisfactory.

The small outbreak of so-called "epidemic dropsy" in Calcutta has completely subsided. No other cases have been reported. Nothing decisive has been discovered by the bacteriological examination of the blood.

Oct. 12th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *The New Sanatorium in connexion with the Liverpool Hospital for Consumption.*

ON Oct. 18th, in the presence of a large and influential number of invited guests, the Countess of Derby formally opened the new sanatorium in Delamere Forest (provided by Lady Willox and Mr. William P. Hartley at a cost of £15,000) in connexion with the Liverpool Hospital for Consumption. The idea of a sanatorium first suggested itself to Mr. Hartley, to quote his own words, "by reading a leading article and also reports of the proceedings under the presidency of the King (then Prince of Wales) at Marlborough House, and the speeches of eminent physicians from all parts of the kingdom." He felt irresistibly drawn to do something towards bringing Liverpool

into line with that great movement for the benefit of patients affected with tuberculosis. He found a willing helper in Lady Willox, the wife of Sir John Willox, M.P. Lady Willox was unfortunately unable to be present at the opening ceremony owing to illness. She had watched the inception and the progress and now the completion of the building with great interest, and it was therefore, I feel sure, a keen disappointment to her not to be able to witness the opening of an institution to which she had contributed so largely. Lady Derby, in declaring the sanatorium open, expressed a hope that it would always continue to prosper and to do good.

### *Liverpool Country Hospital for Chronic Diseases of Children.*

Mr. T. Sutton Timmis has contributed £1000 to the fund now being raised for the erection of the Country Hospital for Chronic Diseases of Children.

### *Liverpool Guardians' Joint Hospital for Tuberculosis at Heswall.*

ON Oct. 25th Mr. Walter Long, the President of the Local Government Board, laid the foundation-stone of the new joint Poor-law hospital for tuberculosis at Heswall. The site for the hospital is very pleasantly situated on the hillside near Heswall, well sheltered from the east winds, and commanding extensive views of the estuary of the Dee and the Welsh coast. The total area of the land is about 15 acres. The buildings are being erected with the main front facing due south. The administrative block will be in the centre, and immediately in front on the first floor will be an open-air sun-bath, divided for the two sexes. On either side of the administrative block will be the two wings, two storeys high, containing dormitories for 24 patients—viz., 12 male and 12 female. To every patient will be allotted 1000 cubic feet of air-space. All the windows will be made to open as casements and all the rooms will be heated when necessary during inclement weather. In the rear of the main building will be the dining-hall, connected by corridors, with cross ventilation, and fitted complete with the usual kitchen and other offices. The water-supply will be from the West Cheshire Waterworks and the drainage will be dealt with on the usual improved lines. The total cost of the land and buildings will be about £12,000. Mr. Long said that none of the duties which had fallen to his lot—and many of them were agreeable—had given him so much and such permanent pleasure as the one which he had performed that day. Sir John Willox, who supported the vote of thanks to the President of the Local Government Board for the interest he had taken in the new hospital, pointed out that three separate boards of guardians had sunk all jealousies and differences and had worked harmoniously in a great and humane work and had so secured to the public of Liverpool a valuable and a useful institution. The day was also auspicious from the fact that Liverpool stood in the forefront in a great philanthropic work, as this would be the first hospital of its kind in the kingdom. The new hospital would not only be a sanatorium for consumptive patients, but also an educational establishment from which they hoped cured patients would take home with them a knowledge of the principles that tended to eradicate consumption.

### *The City Council and the Proposed University for Liverpool.*

The practical unanimity in Liverpool in regard to a separate university was evidenced at the last meeting of the city council in a striking manner, when it was resolved unanimously to apply for Parliamentary powers during the ensuing session to enable the corporation to assist in the foundation and maintenance of such an institution. The question of a large donation at once or an annual contribution may well remain for future consideration, but from the general tenor of the debate it could be seen that the latter alternative was the popular one.

### *Mr. Benn W. Levy and the Honorary Freedom of the City.*

ON Oct. 17th the honorary freedom of the city was conferred on Mr. Benn Wolfe Levy, one of the trustees of the David Lewis fund. It fell to Mr. Levy's lot to administer the large fortune acquired by the late Mr. David Lewis. The money was left to be expended at the discretion of Mr. Levy and his co-legatee, Mr. George Cohen, and seldom has a labour of love been performed with so much zeal, with so much fidelity to what was believed to be the intentions of the donor, or with a greater impartiality towards the

whole body of citizens. The David Lewis Northern Hospital, which is the chief enterprise of the David Lewis trust in Liverpool, has been equipped with every apparatus that modern science can suggest. No expense has been spared to secure the highest efficiency attainable. Mr. Levy also devoted a further portion of the David Lewis trust towards increasing the funds of the Victoria Nursing Institution, which was founded in commemoration of the Diamond Jubilee of Her late Majesty Queen Victoria.

*Cyclists' and Harriers' Parade for the Benefit of the Hospitals.*

The annual cyclists' and harriers' parade, which took place in the early part of the summer, was highly successful, the collection taken along the line of route having proved a record one. The sum available for distribution among the charities was £725. Since the inauguration of the parades in 1892 the cyclists and harriers of Liverpool have distributed among the various charitable institutions connected with the city £3958.

*Plague in Mediterranean Ports.*

In view of the reappearance of plague in certain Mediterranean ports Dr. E. W. Hope (the medical officer of health) has issued a circular letter to the profession inclosing a copy of Dr. Balfour Stewart's memorandum setting forth the diagnostic signs and symptoms of plague, similar to that forwarded from the Health Department in September, 1900.

*Medical Service at St. Luke's Church.*

The service arranged for medical men at St. Luke's Church on Oct. 20th was very successful. About 300 members of the profession attended, seats for whom were reserved in the centre aisle. Besides the wives and friends of the medical men present a large number of nurses occupied the gallery. The sermon was preached by the Lord Bishop, and the collection was devoted to the Medical Benevolent Fund.

*Plague in Liverpool.*

Official information has been received in Liverpool from the Local Government Board that two recent deaths in Everton were due to bubonic plague.

Oct. 29th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*The Senghenydd Colliery Explosion.*

THE inquiry by the coroner into the cause of the death of the 81 men who were killed while working underground in the Universal Pit, Senghenydd, on May 24th last when an explosion occurred was concluded on Oct. 24th. It will be remembered that only one man was rescued alive. Professor W. Galloway conclusively demonstrated a few years ago that the soft smooth coal-dust scattered over the workings is responsible for the transmission of the flame when once a mine becomes fired, and although the jury agreed that this was the case in the particular instance under investigation they found that it was not possible, owing to conflicting opinions expressed by his Majesty's Inspector of Mines and Professor Galloway, to locate the exact spot where the explosion took place. It was stated during the inquiry that there is no statutory obligation upon colliery managers to keep the workings well watered.

*A Defaulting Sanitary Authority.*

The Carmarthenshire County Council has decided to make a representation to the Local Government Board in accordance with the provisions of Section 299 of the Public Health Act, 1875, to the effect that the Llanelly Rural District Council has made default in enforcing the provisions of that Act. The population of the district at the last census was 24,213. That portion of the district known as Burry Port appears to be in the worst sanitary condition, but there are generally lack of drainage, insufficient water-supply, and no means of dealing with cases of infectious disease. The desirability of appointing a county medical officer of health for Carmarthenshire has upon one or two occasions been discussed by the county council, but no disposition has been shown to make such an appointment.

*Sir Frederick Treves at Bristol.*

The first municipal bacteriological laboratory in England

was established a few years ago in Bristol by the medical officer of health (Dr. D. S. Davies) with the assistance of Dr. Walter Dowson, and on Oct. 25th Sir Frederick Treves formally opened a bacteriological department in connexion with the Bristol Royal Infirmary. Later in the day Sir Frederick Treves distributed prizes to the medical students attending University College, and in his address to the students was particularly happy when comparing the history of the successful medical practitioner with the history of the city of Bristol—a town which had made its way without natural advantages and entirely by its own energies and efforts. The annual dinner of the Bristol Medical School was afterwards held at the Royal Hotel, under the presidency of Dr. Markham Skerritt, Sir Frederick Treves being the guest of the evening. There was a large company which included the Lord Mayor and the majority of the members of the local medical profession.

*The Church and Sanitation.*

The question of the housing of the working-classes was discussed both at the Llandaff and at the Hereford Diocesan Conferences which were held last week, and at each gathering there was displayed by those who took part in the discussions very considerable familiarity with the duties and obligations of sanitary authorities. The address of the Rev. C. A. Treherne at Hereford was exceptionally accurate in points of detail and his exposition of the Housing of the Working Classes Act was particularly lucid. The only portion to which exception could be taken was when he advocated the relaxation of the stringency of the model by-laws relating to new buildings. These by-laws are not perfect by any means, but those who are officially connected with sanitary administration are constantly warning us that in those districts where these regulations have not been adopted, or where adopted have not been enforced, there is going on a steady manufacture of slum property which in a very few years will give us as much trouble as that which it is now replacing has done. The Bishop of Hereford suggested that every dwelling-house should be labeled with the name of its owner, who in many instances would be ashamed to be known as the owner of a house unfit for decent habitation. Not only the Bishop of Hereford, but several prominent speakers at the Llandaff conference and at Hereford spoke in strong terms of the necessity for placing the inspection of houses with reference to sanitation and overcrowding in the hands of competent officials who should live away from the districts which they inspect and should have no personal connexion with them. This is equivalent to saying that sanitary officers should not be liable to dismissal at the hands of local authorities merely for capricious or personal reasons. This expression of opinion coming from men of education occupying responsible positions will commend itself to all those who desire to see the public health service placed upon a more satisfactory footing than that upon which it is placed at present.

*Brentry Inebriates' Home.*

The Home Secretary has extended the certificate of this institution to allow of 50 females being admitted in addition to the 150 whom the institution is already authorised to accommodate.

Oct. 28th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*General Council of the University of Edinburgh.*

THE statutory half-yearly meeting of this body was held in Edinburgh on Oct. 25th. Sir William Muir occupied the chair and there was a large attendance. Mr. F. Grant Ogilvie, director of the Museum of Science and Art, and Mr. Campbell Lorimer, advocate, were elected assessors in the University Court in place of Mr. Hope Findlay, W.S., and Mr. Taylor Innes, advocate, whose term of office had expired. The joint report by the business and finance committees was then submitted. It deals with the Carnegie Trust. It points out that the income of the fund amounts to £100,000 per annum, which sum is divided mainly between two purposes: (a) the increase of teaching power and facilities and (b) the payment of class fees of Scottish students. The joint committees under the first head of Mr. Carnegie's gift recommend the General Council to

represent to the University Court that the following are clamant needs of the university—namely:

1. The development of the work of the university in connexion with the teaching of modern languages.
2. The strengthening of the teaching staff in the medical faculty, so that subjects which have recently become of increased importance should be adequately represented.
3. The provision of suitably equipped laboratories for the instruction of students in all graduation subjects for which practical work is required.
4. The establishment of laboratories providing facilities for research in the main lines of scientific work.
5. The improvement of the library.

The next report submitted dealt with the decrease in the number of students. Both reports were adopted. Dr. Richard J. Berry then proposed the following motion of which he had given notice:—

That this council requests the University Court to inquire into the feasibility of reorganising the medical curriculum on the lines suggested by the Pathological Club of Edinburgh.

The lines referred to were practically the inclusion of the present extra-mural school in the university. This motion was remitted to the standing committees for consideration. Dr. Ernest Greville then moved:—

That returns be made showing (a) the number of hours spent by each professor in teaching his practical classes; (b) the number of hours so spent by the assistants; (c) the amount paid by the students for such practical classes. Voting to be by ballot.

This motion was submitted in a speech of considerable length which developed into an attack on Professor Chiene, and the speaker was several times interrupted by the chairman. The previous question having been moved, it was carried by 33 to 21 votes. At the last meeting of the General Council Dr. Greville made an attack upon the conduct of the practical classes which met with much sympathy, although it was felt that the introduction of the names of individual professors was a tactical blunder, however true the statements might be. The question raised is one of very great importance, and it is a pity that it should have been spoilt by personal references which were not essential to it, although they added a certain piquancy and produced a measure of heat on both sides.

#### *Royal College of Surgeons of Edinburgh.*

Dr. J. Halliday Croom has been elected president of this College in succession to Dr. J. Dunsmure.

#### *Volunteer Medical Staff Corps, Glasgow Companies.*

Under the guidance and direction of Surgeon-Lieutenant-Colonel G. T. Beatson, together with the enthusiastic co-operation of the other officers, the progress of the Glasgow companies of the Volunteer Medical Staff Corps has been both sustained and rapid. The organisation is now extended to five companies and candidates for admission are at all times numerous. Under the auspices of the Scottish Committee of the Red Cross Society Surgeon-Lieutenant-Colonel Beatson on Oct. 25th gave a public lecture on Ambulance Work on the Field of Battle. The interest of the occasion was increased by the presence of Major Hautonville Richardson, who explained the employment of dogs as agents for the discovery and assistance of wounded soldiers and exhibited four dogs which he had trained for this purpose. On the following day a practical demonstration of ambulance work was given on the drill-ground at Yorkhill and attracted a large number of the public. The main idea was to illustrate the surgical assistance rendered on the field of battle to a brigade in action, the organisation including the collection of wounded by a bearer company and their conveyance by successive steps to the collecting station, dressing-station, and field hospital. Surgeon-Major W. F. Somerville was in command of the bearer company. The cyclist detachment of the corps gave a special exhibition of the use of the bicycle in ambulance work, and Major Richardson's dogs proved their efficiency by discovering "wounded" who had otherwise been overlooked. The proceedings were highly successful and reflected great credit on all concerned. Many of those who took part in the demonstration have recently returned from active service in South Africa. Quartermaster Lee and Sergeant-Major Kenney are among those who have in this way taken part in ambulance work at the seat of war.

#### *Curious Action against the Glasgow Corporation.*

On Oct. 25th, at the Glasgow Sheriff Court, a claim was

brought against the corporation by the landlords of some house-property. It seemed that there lately resided in the house in question a tenant against whom an ejection order had been obtained which was duly put in force. The tenant, when expelled from the flat, having no other house to which to go, sat down outside the house holding in her arms a child apparently ill. Whilst there she was spoken to by a sanitary inspector, to whom she gave the information that the child was recovering from measles. The inspector then called upon the landlords' agent and suggested that the mother and child should be permitted to return to the house, promising that if this were done he would get the house fumigated. To this the agent consented, but the sanitary authorities did not carry out the fumigation until a month had elapsed, and during this time two tenants left the property, and some vacant flats could not be let in consequence of the reputation of the house occupied by the woman. The landlords therefore claimed for the amount of rent thus lost. On the part of the corporation it was argued that no legal liability was attached to the official proceeding which had been conducted in the interests of the public health. It was urged that the statute provided that the local authority should compensate the owner only for any unnecessary damage caused to his house by disinfection, and that here no such unnecessary damage could be proved. Apart from these and other legal objections the corporation denied the accuracy of the plaintiffs' statements. The sheriff, after hearing the arguments on both sides, found for the corporation with expenses.

#### *The Education of Crippled Children.*

The School Board for Glasgow is making special provision in co-operation with the Queen Margaret Settlement Association for the education of crippled and infirm children unable to attend the ordinary schools. A special class-room has been secured and arrangements have been made to provide the children with food at a moderate charge. Private benevolence has supplied an ambulance wagon for conveying the children to and from the school, also a nurse to accompany the children and to remain with them during the day. The class at present numbers 28, and it is hoped that similar conditions can be established in various parts of the city. To accomplish this, however, the school board will require further financial assistance. Similar work carried on in London receives, it is said, a special grant, and the Glasgow board has determined to apply for a like provision.

#### *Bequests to Glasgow Hospitals.*

By the will of the late Mrs. Janet Rodger a sum of £8000 has been bequeathed to various local charities. The Royal Infirmary receives £3000, the Western Infirmary £1500, the Victoria Infirmary £1000, and Quarrier's Orphan Homes £1500. A gentleman, who prefers to remain anonymous, has presented to Greenock Infirmary an outfit of electrical apparatus, including the appliances required for the Finsen light treatment.

#### *University of St. Andrews.*

The installation of Lord Balfour of Burleigh as Chancellor of the University of St. Andrews took place on Oct. 24th in the presence of a large and brilliant assembly, which included not only the professors and many graduates of the university but also representatives from all the other Scottish seats of learning and a number of members of Parliament. After Lord Balfour had been formally installed he delivered an address in which he discussed the present position of university education. In the evening a reception was held which was attended by upwards of a thousand ladies and gentlemen. At a meeting of the University Court held on Oct. 27th a communication from the General Medical Council notifying the expiration of Professor J. B. Pettigrew's term of office as the representative of the university on the council was read and it was agreed that the appointment to the vacancy should be made at the next meeting of the court.

#### *University College, Dundee.*

An address on the Needs of the College by Dr. James Stuart, Lord Rector of the University of St. Andrews, was delivered on Oct. 25th at a large meeting of students and the general public. Dr. Stuart spoke on the relation of university education to the practical work of life, and asked that £50,000 should be raised in Dundee for the further development of the college. Lord Balfour of Burleigh, who

presided, said that it was essential to secure the foundation of a chair of German language and literature, a chair of geology, and a sub-division of the different branches of chemistry.

Oct. 29th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The Prevalence of Cancer in Ireland.*

THE thirty-seventh annual report of the Registrar-General for Ireland, recently issued, contains some very interesting statistics as to the increased prevalence of cancer shown by the death-rate tables for Ireland, England, and Scotland. Referring to Ireland, the report contains a most valuable coloured map showing the distribution of the disease in that country between the years 1896 and 1900. From this it appears that the mortality varies widely in the different counties, being lowest in Kerry where the rate is 2.76 per 10,000, and highest in Armagh, where the number is 10.9 per 10,000. During the year 1900 no less than 2717 deaths were attributed to cancer, being an increase of more than 60 over the number quoted for the preceding 12 months. During the last 36 years the cancer death-rate has steadily grown from 2.6 to 6.2 per 10,000. It is not any consolation to know that the state of things in England and Scotland seems to be even worse, the mortality line in Great Britain having also risen greatly during the same period. In England the rate per 10,000 has advanced since 1864 from 3.8 to 8.4; in Scotland from 4.2 to 8.2. It is difficult to see where any statistical fallacy can come in to explain away or to modify the unsatisfactory import of these figures.

### *National Association for the Prevention of Consumption and other Forms of Tuberculosis.*

A meeting of the executive committee of the Dublin branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held on Oct. 26th at the house of the Royal College of Physicians of Ireland. The committee expressed great satisfaction with the course adopted by the Local Government Board in issuing the circular letters, leaflets, and posters of the association to all the sanitary authorities throughout Ireland.

### *Jervis-street Hospital, Dublin.*

The inaugural address at Jervis-street Hospital will be delivered on Nov. 6th by Mr. Austin Meldon, D.L., when Viscount Powerscourt will preside. The lecturer will deal with the increasing prevalence of cancer.

### *Medical Poor-law Appointments in Ireland.*

It is difficult for anyone living outside Ireland to understand how politics now enter into such an election as that of a dispensary medical officer of the Poor-law Board. Here are the facts, however, of a recent case. Newport dispensary district in co. Mayo became vacant and two candidates entered the field, Mr. P. J. Heneghan and Mr. A. Gill. The former in his application to the electors said that "he was a member of the United Irish League from the start, and whether elected or not to-day he intended to remain so. .... He was a gold medallist of St. Vincent's Hospital and a student of the Catholic University." At the election he was proposed and seconded, his nominator putting forward a motion "that we refuse the nomination for the Newport vacancy of any doctor who is not a member of the United Irish League." This proposal was lost by only a majority of three. Father O'Toole, a priest, although not a guardian, an elector, or a member of the board, was present and asked the proposer of Mr. Heneghan if he could deny that that gentleman was a student of a Queen's College (Galway) and if he did, said the reverend father, "I will prove it." He also added that "all the priests of the deanery held a private meeting to discuss the question of a medical man for Newport and they decided by a majority in favour of Mr. Gill." It is not necessary to add that Mr. Gill was elected. Mr. Heneghan is to be condemned for introducing politics into his application, and so is his nominator, who would boycott all medical men except those who are members of the United Irish League; but what are

we to think of a medical election when a non-elect who had no right to be present—a Catholic clergyman—entered the board-room and urged that a medical man should not be elected because he attended a Queen's College?

### *The Powers of the Local Government Board for Ireland.*

On Oct. 26th, in Monaghan, a large meeting of gentlemen representative of public bodies in Ulster was held in the board-room of the workhouse, when resolutions were carried proclaiming "entire want of confidence in the Local Government Board for Ireland as at present constituted." "We are satisfied," they added, "from our experience of the board that the administration of local government in this country will remain little better than a farce until the present board disappears and a new board is created, composed of men who have a thorough knowledge of Irish local affairs." Further, "Recognising the necessity which exists for the reconstruction of the Board so that a court of appeal, where equity would be the leading characteristic and where justice would be dispensed without regard to personal or political interest, would be established, we firmly assert that the governing body in Irish affairs should be so selected and constituted that the voice and aspirations of the people should not be subjected to the system of suppression which has hitherto prevailed." A ratepayers' association, it was also decided, should be formed to impede the arbitrary authority of the Local Government Board. There is no question that all over Ireland at present there is a revolt against the system of dictation from various central boards in Dublin.

### *The Armagh Guardians and the Nursing Question.*

The Local Government Board having written to the Armagh Guardians that they were prepared to grant an inquiry upon oath, to be held by a medical inspector, as to the manner in which the medical officer had discharged his duties, it was decided to refer the matter to a committee to report at the next meeting. This report was presented on Oct. 15th at the weekly meeting of the Armagh Board of Guardians. In this report it is said that the guardians were not aware that the medical officer had been accused of any failure in the discharge of his duties except that the Local Government Board in their letter of August 16th drew certain inferences unfavourable to him from the fact that on the date of the inspector's last visit to the workhouse the infirmary and fever hospital nurses were absent from duty for the purpose of taking air and exercise. The guardians did not deny that these nurses were absent and that there were no qualified persons in their places. For this the guardians took full and entire responsibility, as the medical officer on many occasions within the past 12 months had informed the guardians that he considered it necessary that the services of a second qualified nurse should be obtained for day duty in the infirmary. While agreeing with the medical officer that a second nurse was necessary the guardians were convinced that the appointment of an intelligent probationer nurse would be sufficient. The question of the absence of the fever hospital nurse had been fully and satisfactorily explained by the medical officer. As there could not possibly be any further facts to elicit, the committee did not see, therefore, what purpose an inquiry would serve. This report was unanimously adopted by the Armagh Guardians without discussion. The question now is—how the Local Government Board will act. There is also a discussion between the Armagh Board of Guardians and the Local Government Board on the nursing question, the guardians urging that their present staff with the addition of a probationer nurse would be sufficient for all ordinary requirements of the establishment while the Local Government Board demand the appointment of a qualified nurse and refuse to sanction the appointment of a probationer. A special meeting of the board has been called to take the whole matter into consideration.

Oct. 29th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *The French Association of Urology.*

THIS association, to which can belong every French specialist in diseases of the urinary organs, whether

physician or surgeon, opened its fifth annual session on Oct. 24th under the presidency of Professor Guyon. The subject for discussion was "Moveable Kidney, its Pathology and the Indications for Operative Interference."

#### *The Medical Treatment of Adenoid Vegetations.*

At a recent meeting of the Pediatric Society Dr. Lapeyre made a protest against the existing abuse of surgical measures in the treatment of adenoid vegetations during infancy and adolescence. He argued that in many cases it was quite possible, with patience, to obtain a cure by medical measures. The treatment consists in administering iodine in an alcoholic solution. At the beginning six drops are given three times a day and the dose is gradually increased until 40, 50, or even 60 drops are given per diem. Dr. Lapeyre had treated in this way 28 cases of adehoids, the patients varying from five to nine years of age. The treatment had been successful in every case and only very rarely were symptoms of iodism produced. Many of those present confirmed Dr. Lapeyre's statements and added that the internal administration of iodine, combined with local applications of menthol dissolved in oil, had in their hands given excellent results and had enabled the patient to do without surgical intervention.

#### *Chloral Hydrate as a Vesicant.*

At the meeting of the Academy of Medicine held on Oct. 8th M. Hallopeau read a paper upon some researches of M. Bonnet with regard to the vesicating properties of chloral hydrate. This drug vesicates very rapidly and is applied in the following manner. It is spread upon diachylon plaster in the proportion, according to M. Bonnet, of 3 grammes to a superficies of 12 by 15 centimetres. The plaster is then applied to the skin which has been previously anointed with almond oil or vaseline. In about 15 minutes the patient feels a sensation of warmth which increases gradually to burning. The plaster is then removed and the reddened part is covered with cottonwool. At the end of 20 or 30 minutes later a blister has risen and the patient goes to sleep—a fact which shows that with chloral hydrate, as well as with cantharides or any soluble substance, the vesicating agent is absorbed. The sleep produced by chloral hydrate is, however, less inconvenient than the cystitis produced by cantharides. It is as well to be careful all the same, particularly in the case of children, and not to make use of too large a surface of blistering plaster. The practical interest of these researches is much less than it would be had not blistering fallen into such disuse as it has. Blisters of a size capable of provoking cystitis are now hardly ever applied, and in fact they are only used of a very small size as revulsives in ophthalmology or in dermatology as in ringworm, and in such cases chloral hydrate has no particular advantage over cantharides.

#### *The Experimental Treatment of Tetanus by the Method of Bacelli.*

At the meeting of the Academy of Medicine held on Oct. 15th M. Josias laid before the gathering the results of some experimental work performed on goats. This was the method of treating tetanus to which Bacelli called the attention of the first Italian Congress of Medicine held in 1888. The method, which has often been used with success in Italy, has been but rarely tried in France. The tetanus toxin employed by M. Josias was of such a strength as to be fatal in doses of 12 centigrammes per kilogramme of body-weight of the goat. To three goats was administered a quantity of toxin of rather more than three cubic centimetres, and directly the first symptoms of tetanus appeared M. Josias gave the animals one or more subcutaneous injections of a solution of carbolic acid of a strength of 2 per cent. All the goats died, together with the control animal, at the end of four or five days, after having exhibited the usual course of tetanus. These experiments went to prove that carbolic acid exerts no action inimical to the development or course of tetanus, and, moreover, the control animal, which appeared much the more ill at the beginning, survived longer than those animals which had received the greatest quantity of carbolic acid. Although the goat can as a rule easily stand doses of from 0.40 to 0.50 of a gramme of pure carbolic acid M. Josias thought that possibly better results could be obtained with smaller doses and therefore he tried a second series of experiments. No better results were obtained. M. Josias concludes from these experiments that

the Bacelli method of treatment apparently has no favourable influence for the patient upon the evolution of tetanus once the symptoms have declared themselves, and this, too, even if the treatment is begun as soon as the earliest symptoms show themselves.

#### *An Artificial Larynx.*

At the meeting of the Academy of Medicine held on Oct. 22nd, M. Le Dentu showed a most interesting case—that of a patient upon whom M. Jaboulay had performed total extirpation of the larynx. Since the operation the patient had been wearing an artificial larynx by means of which he could speak fluently. At the invitation of M. Le Dentu the patient talked and answered questions, the quality and pitch being unvarying and somewhat high. The larynx is practically a box made in hardened caoutchouc, moulded in the position of the natural larynx and fitting on the top of the trachea. An indiarubber diaphragm with a slit in the middle acts as the glottis and vibrates like it. The tension being always the same it can, however, give but one note. But, as speech is performed by the tongue the palate, and the teeth, pronunciation, although all on one note, is perfect and quite intelligible. A metal grating shuts over the upper part of the larynx and prevents the intrusion of particles of solid food when the patient eats, while fluids are prevented from entering by a circular gutter which leads by a lateral tube into the œsophagus. The patient breathes through an anterior opening like a tracheotomy tube, which is found to be more convenient than breathing through the larynx, and when he wishes to talk he closes this opening with his finger.

(FROM OUR OWN CORRESPONDENT.)

#### *Swiss Universities.*

THE number of medical students is still on the increase, notwithstanding the unpromising forecast as regards lucrative work after the students have obtained their degrees. The total number of students in the summer term of 1901 amounted to 1328, as compared with 1201 for the preceding year, an increase of 9 per cent. The number of students registered at the five Universities is as follows:—Berne 364, Geneva 351, Zürich 305, Lausanne 170, and Bâle 138. The majority of the students are foreigners—viz., 227 male and 490 female students; the number of the latter is considerably on the increase notwithstanding the fact that German ladies can now pass their curriculum at German universities and are admitted to their usual medical examinations. The larger number must also be attributed to the increase of Russian lady students who cannot study in their own country, to the great facilities offered for study at the Swiss universities, and also to the good quality of the clinical instruction and the great opportunities for practical work. Small universities offer these facilities more than the larger schools at Vienna, Berlin, Munich, Leipsic, and Würzburg.

#### *Society for School Hygiene.*

In the education of the masses Switzerland has for many years been in the foremost rank and ever and anon deputies from foreign countries come to study the educational facilities offered gratuitously to everybody residing in Switzerland. So much attention has been paid to education and so much time has been demanded for mental efforts that the physique of the scholars has begun to be threatened. Medical men from time to time have raised a voice of warning, but they have remained practically unheard. Hence the desirability of forming a Society for School Hygiene in which medical men and school authorities could arrive at a mutual understanding with regard to the desired limits of education *versus* physical well-being. An appeal was immediately responded to by hundreds of medical men, professors, and schoolmasters; the Federal and local authorities also took a lively interest in the formation of this society, which was founded last year and now issues its second annual report. Limits of space forbid me from entering into details, but a *résumé* of the proceedings of the July annual meeting held at Lausanne will give an idea of the work that is performed,

in which the best men have joined to protect the physical status of our juvenile world. Professor Combe of Lausanne spoke on the Etiology of Scoliosis and Dr. Scholder of the Orthopædic Institute on the Therapeutics of Scoliosis. Dr. Wilhelm Schulthess of the Zürich Orthopædic Institute read a paper on the Connexion between the Posture whilst Writing and the Deviations of the Vertebral Column. Professor Otth of Lausanne reported on the Advantages of Perpendicular Writing in comparison to the usual Slanting Method of Handwriting. Mr. E. Heuzmann, Music Director at Berne, enlarged on the Hygiene of Singing and the Rational Methods of teaching Singing in Schools, whilst Dr. Schmutziger of Aarau spoke on the Desirability of the Schools beginning later both in Summer and Winter. There is no doubt that this society, which is receiving deserved support from all sides, will continue to do good work and thus the public weal will derive great and lasting benefit.

#### *Decrease of Mortality in Switzerland.*

The Federal Statistical Office at Berne has just published a report with regard to the ratio of mortality in Switzerland from 1871 to 1890. If one considers the mortality-rate in the last decade (1891-1900) the decrease is very striking. Arranged in six groups of five years each the ratio per 10,000 has decreased as follows: 23.8, 23.1, 21.3, 20.4, 19.6, and 17.8, or a decrease of one-fourth in 30 years. This decrease is almost universal, the Cantons of Grisons and Valais being the only exceptions, but it is differently distributed over the various parts of the country. I must mention that the surplus of births over deaths from 1871 to 1890 was 7.3 per cent.

Zürich, Oct. 28th.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

#### *Institute for Medical Research.*

THIS institute, previously mentioned in THE LANCET,<sup>1</sup> has a board of managers made up as follows: Dr. William H. Welch, professor of pathology in the Johns Hopkins University, president; Dr. T. Mitchell Prudden, professor of pathology, Columbia University, vice-president; Dr. L. Emmet Holt, clinical professor of diseases of children, Columbia University, secretary; Dr. C. A. Herter, professor of pathological chemistry, University and Bellevue Medical College, treasurer; Dr. Theobald Smith, professor of comparative pathology, Harvard University; Dr. Simon Flexner, professor of pathology, University of Pennsylvania; Dr. H. M. Biggs, director of the laboratories of the Board of Health. In the summer months, aided by the institute, the milk-supply of the city was investigated and the study of the specific germ which causes outbreaks of dysentery in communities and in institutions was made. The work now taken up relates to phases of tuberculosis and typhoid fever, and other problems closely allied to the cause and prevention of other common diseases. Arrangements have been completed by which 19 persons will within about a month be working on research lines. These men, with one exception, will carry on their work in laboratories in Chicago, Philadelphia, Montreal, Ann Harbor, Boston, Baltimore, Middletown (Conn.), Cleveland, New Haven, the University of California, and in this city. The one exception is Dr. Marshall, a pupil of Dr. Welch of the Johns Hopkins University, the president of the board, who is to study in the laboratory of Professor Ehrlich, in Germany, some of the methods of the latter. Dr. Marshall received a Fellowship of the University and started for Germany some months ago. All the Fellowships and other appointments are for one year. Every person assisted from the funds of the institution is required to do a piece of original investigation and to submit a report of it to the directors of the institution for publication. Each person will receive credit for his work. Some of the communications received by the board since it began its work showed that in its endeavour to obtain tangible results it had sought as soon as possible to learn where capable men with an inclination to labour in research

lines and willing to go ahead with the appliances at hand were to be found. Two reports of much public interest will soon be made to the public by the board. One is the report of the investigation of the milk-supply of the city and the other is the study of the specific germ that causes outbreaks of dysentery. A preliminary report of the milk-supply investigation has been made; a fuller statement will soon be published. What was especially gratifying to the board was that most of the leading milk-dealers and many other persons connected with either the shipping or the transportation of milk to this city were found ready to coöperate in the task of improving the milk-supply. In this investigation three workers were employed; one attended to the inspection of dairies, the hygiene of cow stables, and the handling and transportation of milk, another devoted his time to the bacteriological work, and the third studied the milk-supply of institutions in relation to the health of inmates and also did a little work on similar lines in tenement houses.

#### *Extinction of Leprosy in the Hawaiian Islands.*

Superintendent Reynolds of the colony of lepers states that leprosy is being slowly, but none the less surely, eradicated in the Hawaiian Islands. Five years ago there were over 1300 inmates in the leper settlement on the Island of Molokai; when the annual visit was made a few days ago there were only 900. This is due, not so much to the scientific treatment of the disease, but to the fact that the native race is gradually dying out. Of those who are now inmates of the colony all but 50 are native Hawaiians; there are 15 whites and 30 Chinese. Last year just 100 lepers were sent to the island, but only 50 have been sent in the last nine months. In the biennial period ending December, 1900, directly after the islands had been annexed, over 500 were transferred to the settlement. This was due to the fact that the matter was taken from the hands of the party formerly in charge of such cases, and those afflicted with this disease were hurriedly sent to the place of segregation. Heretofore many such persons have remained in Honolulu through political influence.

#### *Large Increase of Fever in New York.*

The Department of Charities reports that the wards of all the city hospitals connected with the department are filled and that this condition is due to the large number of typhoid fever and malarial patients. On inquiry it was found that there were no vacant beds for new medical cases in most of the large hospitals of the city. In all of them there are certain wards for typhoid fever cases and when these are filled beds in others must be found where there is no danger of any other patient in the hospital catching the disease from those already suffering from it. To find such accommodation quickly is often a perplexing matter. Usually the beds in the surgical wards are brought closer together and the convalescing in-patients are transferred from the convalescents' wards to the surgical wards because they are better able to withstand being removed than any other patients. This expedient has been adopted in many of the city hospitals lately. The officials of the Charities Department think that the increase in fever in the city is due to the opening of the streets for the rapid transit tunnel and for other public works which require the tearing up of the streets.

#### *An International Health Service.*

The members of the United States delegation to the International Conference of American States in Mexico have issued a request for suggestions relating to the possible establishment of an international health service. The proposition is to unite all the American Republics in the prosecution of common measures for the control and final extermination of pestilential diseases, especially of yellow fever. A practicable plan for securing international coöperation for this purpose has been submitted by the Surgeon-General of the Marine Hospital Service and will doubtless form the basis of discussion. This plan is briefly as follows. An International Sanitary Commission is to be created, to consist of five members, no two of whom shall be residents or citizens of the same Republic. They shall be appointed by the Bureau of American Republics and shall serve one year, when they may be reappointed or new members may be selected to succeed them. Of these five members one shall be a diplomat, one learned in the law, one a physician and sanitarian, one a sanitary engineer, and

<sup>1</sup> THE LANCET, June 22nd, 1901, p. 1801.

one a commercial representative. To these five members shall be added, temporarily, two others to represent the national government in whose domain is located the seaport city or town to be investigated or to be subject to sanitary requirements. These two members shall be appointed by the President of their Republic and shall serve only in that Republic. The duties of the International Commission shall be, first, an inquiry of a commercial character to determine upon and to prepare a list of the seaport cities or towns necessary to be visited with a view to sanitary improvement; secondly, to visit the said cities or towns in order of greatest commercial necessity and with the two additional commissioners to make a thorough sanitary inspection of the port and city or town and formally to report upon the sanitary measures deemed necessary, keeping within the limits of this convention; thirdly, this report shall be in duplicate signed by the seven members of the commission. One copy shall without delay be transmitted to the President of the Republic within whose domain the city or town inspected is located and the other copy shall be sent for file to the Bureau of American Republics. Immediately after the receipt of this report it shall be the duty of the President to whom it is sent to take such action as lies within his power, either through national, State, or municipal authority, to put into effect the measures recommended by the commission or other effective measures satisfactory to a majority of the commission of seven and so certified in writing. If one year from the date of the receipt of the report of the commission by the Bureau of American Republics work has not actually been begun, or if plans have not been prepared and contracts made, it shall be the duty of the Bureau of American Republics to notify each of the nations entering into this convention, and each of the said nations obligates itself thereupon immediately to impose upon vessels arriving from the said ports additional tonnage tax and duties upon specified imports.

#### *The Study of Yellow Fever.*

The Supervising Surgeon-General of the United States Marine Hospital Service has prepared and submitted to the Secretary of the Treasury a plan for the organisation of an association whose object it will be to collect all facts concerning yellow fever, to designate the specific lines of investigation to be made and to make the investigations. The members of the institute are to be the medical officers of the United States Marine Hospital Service and others especially qualified. They will be assigned for duty to one of four sections, each section having a special list of topics for consideration. Each of the four sections will be under the direction of one of the medical officers on duty in this bureau, and the said bureau officers, with the director of the hygienic laboratory, the Surgeon-General, and a secretary will constitute an executive board which is to have general oversight of all the investigations. This furnishes a convenient method of administration, as the machinery of the institute will be readily worked in the Bureau, while the actual labour will be carried on by members in various places. The stimulus to the members will be not only the scientific interest in the subject, but the publication of their contributions in the shape of bulletins as often as it seems advisable to the board, while the department will find the funds necessary for incidental expenses. In these circumstances it is believed that the organisation will meet with a degree of success warranting its existence.

Oct. 18th.

## Obituary.

JOHN HALLILAY, L.K.Q.C.P. IREL., M.R.C.S. ENG.

By the death of Mr. J. Hallilay, which occurred at his residence, Moorland-road, Leeds, on Oct. 21st, the medical profession of the city lose one of their oldest and most esteemed *confrères*, while a wide circle of patients deplore the removal of a trusted medical adviser and friend. Mr. Hallilay was born at Wakefield and entering Guy's Hospital attended the lectures of Bransby Cooper and Thomas Addison, who first described Addison's disease.

Mr. Hallilay commenced practice in Leeds nearly half a century ago, and until a paralytic seizure compelled him to retire was a familiar figure in the life of the city. As a practitioner he was eminently safe, his judgment was sound, while his diagnosis and treatment of a case, as might be supposed from the celebrated teachers he followed, were marked by deliberation and care. Mr. Hallilay was a Churchman and in politics was a staunch Conservative. He was also an enthusiastic Freemason. For many years he acted as one of the stewards of the West Riding Medical Benevolent Fund. He was twice married and leaves a widow and three sons, two of whom follow their father's vocation. Mr. Hallilay's character was that of a simple, unostentatious gentleman, while his kindly, sympathetic, and generous disposition rendered him beloved by all who knew him.

## Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Examination in Sanitary Science held in October the following candidates satisfied the examiners in both parts of the examination for the Diploma in Public Health:—

John James Buchan, Frank Marsden Burnett, Archibald Fawns Cameron, Harold Selwyn Capper, John Morton Sim Coutts, John Crawford, Frederick Dittmar, John Edward Dowling, Duncan Forbes, Grace Haxton Giffen, Kenneth Weldon Goadby, James Doig McCrindle, John Watterson Miller, William Paul Rodrigo, Parash Ranjan Roy, Harold Robert Dacre Spitta, Hubert John Starling, John Stoddart, Blackworth Stuart, Alfred Jefferis Turner, Douglas Percival Watson, and William Wright.

At the meeting of the Plymouth School Board held on Oct. 22nd Dr. W. Cheyne Wilson was unanimously elected to fill a vacancy on the Plymouth School Board.

THE LATE MR. JOHN GRIFFITH.—The *St. Mary's Hospital Gazette* for October publishes as a supplement a very good portrait of the late Mr. John Griffith, the ophthalmological assistant to the hospital, whose untimely death we recorded with regret in our columns recently.

PRESENTATIONS.—At a dinner held in Bristol on Oct. 18th the members of the Netham branch of the St. John Ambulance Association presented Dr. James Young with a silver cigarette case, suitably inscribed, as a mark of appreciation for his services as honorary lecturer of the class.—Mr. E. B. Fuller, M.B., Edin., late medical officer of health of Cape Town, was recently presented by the staff of the sanitary department of Cape Town with a clock in recognition of his long connexion with the city and of his unremitting work during the recent plague epidemic.

EPSOM COLLEGE.—The enlarged laboratory and lecture theatre, the cost of the extension of which has been partly defrayed out of a legacy of £500 from the late Mr. Maddock, a master at the College, were formally opened on Saturday, Oct. 19th, when there was a large gathering of friends of the College. Amongst those present were Sir W. S. Church, Bart., President of the Royal College of Physicians of London, Dr. Holman (treasurer), the Rev. E. W. Northey, Mr. Christopher Heath, Mr. H. M. Macpherson, Mr. E. K. Robinson, Dr. M. Baines, Dr. S. Felce, Dr. J. H. Galton, Mr. H. W. Kiallmark, Dr. F. Needham, Mr. Bilton Pollard, Mr. C. L. Smiles, Mr. H. E. Vardon, and Colonel Gordon Watson. Before the proceedings commenced Dr. Holman, who has taken the keenest interest in the extensions, entertained a large party at luncheon at the "Spread Eagle," after which his guests were driven to the College to inspect the new lower school, the enlarged chapel, and the newly-fitted laboratory. After a few words from the head-master in the big school-room the visitors adjourned to the new lecture theatre, where the deputy chairman of the council, the Rev. E. W. Northey, in declaring the buildings to be open, observed that the extensions would not only be of the greatest possible use to the head-master but would also be a memorial to Mr. Maddock. He drew attention to the difference between the teaching of science in these days as compared with the instruction given in his younger days. The head-master referred to the great

need there had been for the additions which had just been made and thanked the council in the name of the school for the well-equipped laboratory which contained numberless devices and inventions for saving time and trouble. Mr. Robinson, the late Mr. Maddock's executor, expressed his pleasure that the council had devoted the legacy from his friend to so useful a purpose. The visitors then went over the laboratory and inspected the fittings, apparatus, benches, &c., general satisfaction being expressed with the increased accommodation and means provided for scientific teaching.

**THE LATE MR. B. C. KENDALL.**—Mr. Bernard Charles Kendall died at his residence, Helston, Cornwall, on Oct. 24th from acute laryngitis, after a short illness, in his thirty-sixth year. He received his medical education at the Bristol Medical School and Guy's Hospital, and became qualified as L.R.C.P. Lond. and M.R.C.S. Eng. in 1892. After holding a resident appointment at the Bristol Royal Infirmary he commenced practice at Helston, and three years ago he was returned at the head of the poll for the Helston Town Council.

**LITERARY INTELLIGENCE.**—Messrs. Charles Griffin and Co. have arranged for the publication of "The Work of the Digestive Glands," by Professor Pawlow, of St. Petersburg, translated into English by W. H. Thompson, M.D., M.Ch. R.U.I., F.R.C.S. Eng., Dunville Professor of Physiology, Queen's College, Belfast, and Examiner in Physiology, Royal College of Surgeons of England and Royal University, Ireland. Professor Pawlow's researches were recently awarded the Nobel prize of £11,000. This edition, which will include the notes of the most recent researches of Professor Pawlow and will constitute the sole authorised edition for England and America, is ready for immediate issue.

**BORIC ACID IN BUTTER.**—Messrs. Pearks, Gunston, and Tee, grocers, having appealed against a fine of £50 inflicted for selling butter containing boric acid the case was heard at Folkestone Quarter Sessions before the Recorder, Mr. Lewis Coward. The only witness called was Dr. M. K. Robinson, medical officer of health of the East Kent combined district, who was of opinion that boric acid taken constantly in small quantities was prejudicial to health. In the cross-examination counsel for the appellants made use of the fact that boric acid was alleged to be harmless by Professor Liebreich of Berlin University, Professor Chittenden of Yale University, and Professor Tunnicliffe of King's College, London. The Recorder, having been informed that these authorities had not been quoted before the justices, thereupon quashed the conviction.

**FREEMASONRY.**—*The Middlesex Hospital Lodge, No. 2343.*—A meeting of this lodge was held on Oct. 17th at Freemasons' Hall, W. Bro. T. G. A. Burns, M.R.C.S. Eng., being in the chair. Bros. Baldwin, Milburn, Dutton, Noel, and Mulvey were admitted to the second degree. Mr. D. B. Balding, F.R.C.S. Eng., Mr. Campbell Thomson, M.D. Lond., and Mr. Peter Thompson, F.R.C.S., were initiated into Freemasonry, and Bros. Lionel Litchfield Preston, M.B., B.S. Durh., M.R.C.S. Eng., and Philip Barnett Bentlif, M.R.C.S. Eng., were unanimously elected Joining Members of the lodge. The brethren and guests afterwards dined together. *The Cavendish Lodge, No. 2620.*—The Cavendish Lodge met on Oct. 16th, at the Royal Palace Hotel, Kensington. Dr. J. Allan (Chislehurst) and Mr. Chaldecott (London) were admitted into Freemasonry by the W. M. (Bro. Bidwell), and afterwards the Installation ceremony took place, Bro. Percy Dunn, being the W.M. for the ensuing year. The ceremony was performed by W. Bro. Bidwell. A Past Master's jewel was then presented to W. Bro. Bidwell. The W.M. next invested his officers, as follows: I.P.M., W. Bro. Bidwell; S.W., Bro. Menzies; J.W., Bro. Cathcart; Treasurer, Bro. Gunton Alderton; Secretary, W. Bro. Mortimer; Organist, Bro. W. Nicholl; S.D., Bro. Tuke; J.D., Bro. Handfield Jones; I.G., Bro. McCann; Steward, Bro. Victor Corbould. The brethren afterwards dined together, the members and guests present exceeding 40 in number.

**BEQUESTS AND DONATIONS TO HOSPITALS.**—By the will of Mr. Thomas Edward Wheatley of Norham-lodge, Oxford, £500 each are left to the Manchester Royal Infirmary and St. Mary's Hospital, Manchester.—By his will

Mr. John Hatchell of Fortifield House, Ferenure, Dublin, bequeathed £500 each to the King's Hospital, the Meath Hospital and County Dublin Infirmary, and the Dublin Royal Hospital for Incurables, £100 each to the Adelaide Hospital and the Fever Hospital, and £50 each to the Harold's Cross Refuge for the Dying, the Children's Hospital, and the Hospital for Consumption.—By the will of Mr. James Plumbridge of Glen Lynn, South Croydon, the Croydon General Hospital receives £200 and the reversion of a further sum of £200, and the Miller Hospital at Greenwich £200.—By the will of Miss Isabella Manbey of Brighton personalty of the net value of £27,321 14s. 6d. is bequeathed in trust for the Sussex County Hospital, the Brighton and Hove Dispensary, and three other institutions. From the residue of the estate a further sum of £1000 is left to the Sussex County Hospital.—The Paddington-green Children's Hospital has received from its chairman and treasurer, Mr. George Hanbury, a donation of £100 for current expenses and £200 towards the purchase money required for the new convalescent home, Fair View, Slough—namely, £1200.—The Royal Free Hospital has received a donation of £1000 from George Courtauld to endow a bed in memory of his daughter, the late Miss Louise Courtauld.—The High Sheriff of Gloucester (Mr. J. Bruton) has given £50 to the Gloucester Infirmary in lieu of the customary banquet to members of the corporation.

### BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, 156, Charing-cross-road, W.C.

An Idler's Calendar: Open-air Sketches and Studies. By G. L. Apperson. Price 3s. 6d. net.

Society Snapshots taken at Random on a Trip through the World. By Cotsford Dick, author of "The Model, and other Verses," "The Ways of the World" (Vers de Société). Price 6s.

CHURCHILL, J. & A., 7, Great Marlborough-street, W.

A Short Practice of Midwifery, embodying the Treatment Adopted in the Rotunda Hospital, Dublin. By Henry Jellett, B.A., M.D., B.Ch., B.A.O. Dublin Univ., F.R.C.P. Irel., L.M. With a Preface by W. J. Smyly, M.D., T.C.D., F.R.C.P. Irel. Third edition, revised and enlarged. Price 8s. 6d.

The Pharmacopœia of the Hospital for Diseases of the Throat, Nose, and Ear, Golden-square. Edited by H. Lambert Lack, M.D. Lond., and Charles A. Parker, F.R.C.S. Edin. Sixth edition. Price 2s. 6d.

DEUTICKE, FRANZ, Leipzig and Vienna.

Die Syringomyelie. A Monograph by Dr. Herman Schlesinger, Privat-docent, Neurologisches Institut, Vienna University. Second revised and enlarged edition. Price M. 17.

G. P. PUTNAM'S SONS, New York and London.

The Care of the Consumptive. A Consideration of the Scientific Use of Natural Therapeutic Agencies in the Prevention and Cure of Consumption; together with a Chapter on Colorado as a Resort for Invalids. By Charles Fox Gardiner, M.D., of New York. Price not stated.

HOEPLI, ULRICO, Milan.

L'Epilessia. Etiologia, Patogenesi, Cura. By Dr. Paolo Pini. Price L. 2.50.

Chimica Clinica. By Dr. Raffaele Supino of Pisa. Price L. 2.

**Small-pox: its Prevention, Treatment, and History.** Price 6d.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ARMOUR, T. R. W., M.B., has been appointed House Surgeon to the Hospital for Women, Liverpool, vice W. J. Jones, M.B., M.R.C.S., resigned.

CALTHROP, GORDON, M.B., B.C. Camb., has been appointed Certifying Surgeon under the Factory Acts to the Wells District of Norfolk.

DONALD, F., M.R.C.S. Eng., L.S.A., has been re-appointed Medical Officer of Health for the Ham Urban District.

FALCONER, DONALD GORDON, M.B., M.S. Aberd., has been appointed Certifying Surgeon under the Factory Acts for the Foyers District of Inverness-shire.

FARQUHARSON, A. C., M.B., M.S. Glasg., has been appointed Medical Officer of Health for the Auckland Rural District.

GARDINER, PETER, M.D., C.M. Glasg., D.P.H. Lond., has been appointed Honorary Medical Officer to the Camborne Dispensary.

GREY, T. CAMPBELL, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Medical Officer to the Camborne Dispensary.

HAWTHORNE, C. O., M.D., M.R.C.P., has been appointed Assistant Physician to the North-West London Hospital.

HUNT, E. L., has been appointed Certifying Surgeon under the Factory Acts for the Sherston District of Wilts.

LANCASHIRE, GEORGE H., M.R.C.S. Eng., L.R.C.P. Lond., M.D. Brux., has been appointed Assistant Physician to the Manchester and Salford Hospital for Skin Diseases.

MORRIS, T. H. P., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Halesworth District of Suffolk.

SLADEN, REGINALD J. LAMBERT, M.R.C.S., L.R.C.P. Lond., has been appointed Senior Resident Surgeon to the Royal Sea Bathing Hospital, Margate.

SPENCE, JOHN W. L., L.R.C.P., L.R.C.S. Edin., has been appointed Clinical Assistant to the Electrical Department of the Royal Infirmary, Edinburgh.

THOMAS, J. TELFER, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Medical Officer to the Camborne (Cornwall) Dispensary.

WHITTINGTON, C. E., L.S.A., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Tuxford District of Notts.

WILLEY, FLORENCE ELIZABETH, M.B., B.Sc. Lond., has been appointed Assistant House Surgeon to the Free Hospital, Gray's Inn-road.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

**BARNWOOD HOUSE HOSPITAL FOR THE INSANE, Gloucester.**—Junior Assistant Medical Officer. Salary £150 per annum, rising to £170.

**BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.**—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

**BRACEBRIDGE ASYLUM, near Lincoln.**—Junior Assistant Medical Officer, unmarried. Salary £125 per annum, with apartments, board, attendance, &c.

**BRADFELD UNION.**—Medical Officer and Public Vaccinator. Salary £53, and fees amounting approximately to £35 per annum. Also Medical Officer for the Workhouse, Bradfield. Salary £80 per annum.

- BRENTFORD UNION.**—Assistant Medical Superintendent of the Infirmary and Assistant Medical Officer of the Workhouse and Schools at Isleworth. Salary £100 per annum, with apartments, rations, washing, &c.
- CENTRAL LONDON OPHTHALMIC HOSPITAL,** Gray's Inn-road, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.
- CHelsea HOSPITAL FOR WOMEN,** Fulham-road, S.W.—Registrar. Honorarium 20 guineas per annum.
- COUNTY ASYLUM,** Mickloover, Derby.—Senior Assistant Medical Officer. Salary £130, rising to £150 per annum, with apartments, board, washing, and attendance. Also Junior Assistant Medical Officer. Salary £110, rising to £130 per annum, with apartments, board, washing, and attendance.
- COUNTY ASYLUM,** Lancaster.—Assistant Medical Officer, unmarried. Salary £150, increasing to £200, and on promotion to £250, with apartments, board, washing, and attendance.
- COUNTY ASYLUM,** Prestwich, Manchester.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £250, with board, apartments, and washing.

Curtis and Harvey's Powder Mills, at Hounslow and East Bedford, in the county of Middlesex; at Rainham, in the county of Essex; and at Kirkintilloch, in the county of Dumbarton.

## Births, Marriages, and Deaths.

### BIRTHS.

- PHILLIPS.**—On Oct. 24th, at Bedford-place, Sidmouth, the wife of F. Addison Phillips, M.R.C.S., L.R.C.P. Lond., of a son.
- WILLIAMS.**—On Oct. 29th, at Rotorua, Harrow-on-the-Hill, the wife of Dr. A. H. Williams, of a son. New Zealand papers please copy.
- WOODHEAD.**—On the 27th inst., at Chisholme, Sale, Cheshire, to Dr. and Mrs. H. Miall Woodhead, a daughter.

### MARRIAGE.

- ANDERSON—RICHARDSON.**—At Holy Trinity Church, Pittlochy, on the 23rd inst., by the Very Rev. the Dean of Brechin, assisted by the Rev. Canon Bowstead, Kilmavonaig, John Anderson, M.B., C.M. Edin., to Catherine Mary, only daughter of Captain and Mrs. Richardson, Castle Beigh. No cards.

### DEATHS.

- BUTLER.**—On Oct. 27th, at Millom, Cumberland, Leonora, youngest daughter of Percy Butler and Mary Stoney, aged 20 years.
- NEUBOLT.**—Oct. 28th, at 42, Catherine-street, Liverpool, in her 37th year, Mary Jane, wife of George Neubolt, M.B., F.R.C.S.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### THE CONSEQUENCES OF AN ERRONEOUS DIAGNOSIS.

ON Oct. 23rd Mr. R. B. Rodd, the coroner for the county of Devonshire, resumed an inquest into the circumstances connected with the death of Francis Evans of Quarry-street, Stonehouse. At the previous hearing the daughter of the deceased stated that on August 17th her father had stumbled while crossing the room and had fallen against the dresser, hurting his side. Mr. W. H. Waterfield was called in, and, according to the daughter, stated that Evans was suffering from a cold in the kidneys, pleurisy, and inflammation. Three weeks later Mr. Leah was called in; he stated in evidence that on Sept. 1st he found deceased suffering from a fractured rib on the right side. Bandages were applied and the patient got better. On Oct. 5th Mr. Leah was again called in and found Evans suffering from congestion of the lungs. Death took place "on Saturday"—we presume Oct. 12th—from pneumonia, accelerated by the fractured rib. The inquiry was then adjourned to enable a post-mortem examination to be made and also to give Mr. Waterfield the chance of making a statement. At the adjourned inquest Mr. Leah said that he had made an examination of the body in the presence of Mr. Waterfield. There was no fracture of the ribs. There were pleurisy with adhesions and pneumonia of the right lung. There was also gangrene of the right lung. The kidneys were waterlogged, probably due to septic poisoning from the pulmonary gangrene. There was evidence of bruising over the fifth, sixth, and seventh ribs. Mr. Waterfield deposed that deceased came to him on Saturday, August 24th. He was suffering from pneumonia of both lungs and pleurisy of the left lung in addition. Witness told him to go home, to go to bed, and to be well poulticed. He was not to leave his bed until he got better. Witness asked if he should call the following day, but deceased said "No." Witness called on August 26th and 28th and found deceased better. He did not see him professionally again, but later witness saw deceased walking about in the street. Neither deceased nor his daughter said anything about any injury. Witness was present at the post-mortem examination. There was no fracture of the ribs or any sign of such, but there were pleuritic adhesions over three of the ribs. There were signs of syphilis both internal and external. There were no signs of any external injury over the ribs. In his opinion deceased died from pneumonia, pleurisy, and the general condition due to drink, syphilis, and exposure. The jury brought in a verdict of "Death from natural causes," adding as a rider, "We are of opinion that the inquiry was quite unnecessary and was brought about by an error of judgment on the part of Mr. Leah, and we exonerate Mr. Waterfield from all blame." With this verdict we quite agree. Mr. Leah obviously made a mistake in his diagnosis—a mistake, however, which had no influence on the case either for good or for evil. But according to the question of a jurymen at the inquiry on Oct. 23rd Mr. Leah appears at the former inquiry to have attributed negligence to Mr. Waterfield and to have implied that his failure to diagnose the fracture (which did not exist) had imperilled Evans's chance of getting well. It is better, perhaps, to say that a patient has a fractured rib when he has not than to make the converse error; but to attribute negligence to a fellow practitioner for not finding a condition which is not there is, to say the least, unprofessional. Evans was evidently a bad subject for any disease, and for a man in his condition to go "about the streets and into public-houses," to quote the coroner, is to court death.

### HOME FOR ILLEGITIMATE INFANTS.

To the Editors of THE LANCET.

SIRS.—Can you, or any of your readers, tell me of an institution in which an illegitimate infant would be kept? The mother is poor, but belongs to a respectable family, and we want to save the friends from the exposure if possible. I am, Sirs, yours faithfully,

Oct. 28th, 1901.

ACCOCHEUR.

### WANTED—A HOME.

To the Editors of THE LANCET.

SIRS.—Could you, or any of your readers, inform me of a suitable home for a blind woman, about 50 years of age? She could afford up to 15s. per week. I am, Sirs, yours faithfully,

Oct. 27th, 1901.

J. P.

### "A COMMISSION OFFERED."

IN THE LANCET of Oct. 27th, 1900, p. 1250, we drew attention to the improper methods of the Century Thermal Bath Cabinet Company. This company has now started an "Eastern Branch," the address of which is Arbour-street, E., and from a circular sent out, and signed "H. A. Spurling," we learn that medical men are offered a commission of 10s. 6d. on every cabinet ordered from the Eastern Branch on their recommendation by their clients and friends. The pictures of young women "cooling off" still accompany the circular and there is also a list of "only a few of the hundreds of physicians who are using the

Century Thermal Bath Cabinet in their own families, many of whom are recommending it to their patients." We wonder whether all the physicians whose names appear in this list have been bribed in the way above indicated, and although we do not suppose that such is the case, still, anybody allowing his name to appear in such a list lays himself open to the suspicion of having accepted 10s. 6d. per Century Thermal Bath Cabinet sold through his recommendation. We can only advise all medical men to have nothing to do with a company which employs such questionable methods to increase its trade.

#### THE UNQUALIFIED ASSISTANT.

To the Editors of THE LANCET.

SIRS,—I beg to inclose a cutting from the *Daily Mail* of Oct. 23rd by which you will see that Judge French decided that the employment of an unqualified assistant is not an illegal act. As this decision seems quite the opposite from the last issue from the General Medical Council in which the employment of unqualified assistants has been made a penal offence, I should, in the interest of the profession at large, be obliged if you would in your next issue inform me whether (1) this ruling will stand as a precedent in case of defence; and (2) whether the passing of that Act forbidding the employment of an unqualified assistant by the General Medical Council has been obtained by a special Act of Parliament.—I am, Sirs, yours faithfully,

Fyrland-road, N., Oct. 28th, 1901.

M. Blok.

\* According to the *Daily Mail* in an action in which a medical practitioner sued for fees for services rendered by his unqualified assistant to the defendant His Honour Judge French said that the medical practitioner was entitled only to fees for his own visits, although it was not illegal for him to employ an unqualified assistant, provided that the assistant was not held out to be a qualified medical practitioner. There appears to be a confusion in the mind of our correspondent, Mr. Blok, between that which is an infringement of the law of the land, dealt with as such before a judge or magistrate (as, e.g., when an unqualified person wilfully and falsely pretends that he is a registered medical practitioner) and that which is an infringement of the etiquette of the medical profession dealt with as such by the General Medical Council (as, e.g., when a medical practitioner advertises, or, to take our correspondent's example, when he employs an unqualified assistant). Only a registered medical practitioner is entitled to recover fees for medical and surgical attendance, and it naturally follows that he cannot recover fees in respect of work done by an assistant which the assistant would not be able to recover for himself. The employment of an unqualified person to practise medicine could hardly be made illegal without making unqualified practice illegal in itself, of which at present there appears to be no prospect, but the employment of an unqualified assistant to compound or dispense poisons by a medical man keeping an open surgery is illegal under the Pharmacy Acts.—Ed. L.

#### FREE TRADE IN VENEREAL DISEASE.

THE following lines were picked up in the board-room of a hospital and evidently refer to certain active demonstrations in the cause of purity which we have had before now occasion to find fault with in THE LANCET.

Contagious diseases  
Some ladies it pleases  
To take as their hobby,  
And rail at a Bobby  
When duty compels him  
And Parliament tells him  
To take up a lady  
Whose habits are shady;  
And make an inspection,  
Despite her objection,  
Whereby, if infected,  
She's promptly detected,  
And placed in seclusion  
Until the conclusion  
Of indisposition  
Has made her condition  
No longer a terror  
To youth in its error.  
They say, "It were better  
To look on and let her

Spread loathsome contagion,  
That so it may rage on  
And prove a prevention  
To vicious intention!"

But Physical Evil,  
The child of the Devil,  
Was never intended  
With Good to be blended.  
So, "Good doctor, detain her!  
Good Guardians, maintain her!  
Till taint of pollution  
Is lost in ablution."

Methinks, if the ladies  
Whose mission or trade is  
To stump on a platform  
Would argue in that form,  
Why, a healthier nation  
Would bless their vocation!

#### THE TREATMENT OF THE DROWNED.

To the Editors of THE LANCET.

SIRS,—I have carefully studied the lectures in the June and July issues of THE LANCET of this year, delivered by Dr. Bowles. Not knowing where to get a description of the Marshall Hall method of resuscitation of the drowned I trust you will be kind enough either to send me a copy of the instructions or the address where I could obtain one. Perhaps one of your readers will give me the information.

I am, Sirs, yours faithfully,

Oct. 24th, 1901.

P. T.

#### ADVERTISEMENT.

To the Editors of THE LANCET.

SIRS,—You have exerted yourselves so frequently in attempting to protect the profession from the annoyance of receiving offensive circulars by post, that I venture to draw your attention to the worst

example of this kind of advertising that I have yet seen. Some days ago I received by book post, and inclosed only in an ordinary wrapper, a pamphlet entitled, "The Radical Treatment of Piles and Prolapsus Ani," purporting to be written by a Dublin hospital surgeon whose name and distinctions it bears. On the title-page is written my name, "with the author's kind regards," and on glancing down the page I find the date of publication to be 1889. As the author is entirely unknown to me personally I am quite at a loss to know why I should be the recipient of his kind regards and 12-year old pamphlet, unless it be due merely to the fact of my name being in the Directory. I should say that the circular was addressed not to my professional but to my family address.

I am, Sirs, yours faithfully,

Oct. 29th, 1901.

A DUBLIN PHYSICIAN.

#### THE OBLIGATION TO ATTEND A CASE.

A CORRESPONDENT sends us the following two questions:—(1) Can a medical man refuse to attend a case if his fee is offered? and is he liable for damages if it is proved that death is caused through his non-attendance, there having been no previous engagement? (2) Is there any law or rule of the General Medical Council to compel a medical man to attend in a case of emergency? The answers are:—(1) A medical man is at liberty to refuse to attend a case, but he should never do so for any trivial reason or unless he knows that the case cannot possibly be serious. (2) The answer to the first question applies to the second.

HER MAJESTY QUEEN ALEXANDRA has consented to become patroness of the St. Mary's Hospital for Sick Children at Plaistow.

S. E. S.—Generally speaking Florida has an excellent climate and is much used as a winter resort by invalids from the Northern States of America. St. Augustine on the east is one of the chief resorts and the climate there is similar to that of Italy and the south of France. The hotel accommodation is, we believe, fairly good. Jacksonville is the chief distributing centre of commerce between Florida and the North. A certificate of satisfactory examination by the State (or a district) board of medical examiners is necessary. Diplomas confer no right to practise.

H. B. will find that the question that he asks was answered in the current Students' Number, THE LANCET of Sept. 7th, 1901.

Subscriber.—Our correspondent will find a list of books in the Students' Number of THE LANCET, Sept. 7th, 1901, pp. 634 to 636.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY (4th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (5th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

## SOCIETIES.

**TUESDAY (5th).**—PATHOLOGICAL SOCIETY OF LONDON (Jenner Institute of Preventive Medicine).—8 P.M. Laboratory Meeting. Dr. A. Macfadyen and Mr. S. Rowland: (1) Investigations on Intracellular Constituents; (2) Demonstration of Methods of obtaining Intracellular Constituents; (3) Some Results already obtained as regards the Bacillus Typhosus.—Mr. A. Moore: The Isolation of the Typhoid Bacillus.—Mr. G. F. Petrie: The Hemolysis of Bacillus Pyocyaneus.—Mr. J. B. Leathes: (1) On the so-called Mucous Intestinal Casts (Mucous Colitis); (2) On the Products of Splenic Proteolysis.—Mr. A. Harden: On Isotonic Culture Media.—Mr. A. Mackenzie: The Artificial Preparation of Active Bacillus Hydroxybutyric Acid of Urine.—Mr. S. G. Hedin: Proteolytic Enzyme of Fibrin. Specimens.—Dr. A. Macfadyen: Experimental Tuberculosis in a Monkey.—Mr. A. Moore: Apparatus for Sub-cultivating Microscopic Cultures.

**WEDNESDAY (6th).**—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Specimens will be shown by the President, Mr. Bland-Sutton, Dr. Handley, Dr. Lewers, Mr. Doran, and Dr. Galabin. Paper.—Mr. A. Doran and Dr. C. Lockyer: Sloughing Fibroid of the Left Uterine Cornu, Abnormal Relations.

**THURSDAY (7th).**—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Mr. B. Browne: Twenty-five Years' Experience of Urinary Surgery in Children. (Harveian Lecture.)

**RÖNTGEN SOCIETY** (20, Hanover-square, W.).—8.30 P.M. Mr. H. Jackson. Presidential Address.

**CHILDHOOD SOCIETY** (Library of the Sanitary Institute, Margaret-street, W.).—8 P.M. Lecture.

**NORTH-EAST LONDON CLINICAL SOCIETY** (Tottenham Hospital).—4 P.M. Clinical cases will be shown by Dr. Trevelyan, Dr. Willoughby, Dr. Whiting, and others.

**FRIDAY (8th).**—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers.—Mr. B. G. Moynihan: The Operative Treatment of Cancer of the Pyloric Portion of the Stomach.—Mr. T. H. Morse: Case of Intracranial Section of the Second and Third Divisions of the Trigeminal Nerve for Severe Neuralgia.—Mr. W. Haward: A Case of Fragilitas Ossium.

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM** (11, Chandos-street, Cavendish-square, W.).—Dr. A. H. Thompson: Section of Orbital Tumour (? Endothelioma ? Adeno-sarcoma).—Mr. E. Nettleship: Chronic Serpiginous Ulcer of Cornea (Mooren's Ulcer).—Dr. W. E. Thomson: Three Cases of Keratitis in the New-born occurring after Instrumental Delivery and Resulting in each case in an almost identical Rare Form of Opacity.—Dr. C. O. Hawthorne: On Intra-cranial Thrombosis as the cause of Double Optic Neuritis in Cases of Chlorosis.

**BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION** (11, Chandos-street, Cavendish-square, W.).—4 P.M. Annual General Meeting.—Communications will be read and cases shown by the President, Mr. L. Browne, Dr. Abercrombie, and Mr. Nourse. 5 P.M. Address.—The President-Elect (Dr. J. Macintyre, Glasgow): The Application of Physical Science to the Surgery of Diseases of the Throat and Nose.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &amp;c.

**MONDAY (4th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. R. Crocker: Clinique. (Skin.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Edwards: Electrical Examination of the Bladder and Urethra.

**TUESDAY (5th).**—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. J. S. Bury: Prognosis in Relation to Disease of the Nervous System. (Bradshaw Lecture.)

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22, Chancery-street, W.C.).—4 P.M. Dr. J. Taylor: Clinique. (Medical.)

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC** (Queens-square, Bloomsbury).—3.30 P.M. Dr. A. Turner: Locomotor Ataxy.

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Minor Surgery.

**WEDNESDAY (6th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. J. Cantlie: Clinique. (Surgical.)

**LONDON THROAT HOSPITAL** (204, Great Portland-street, W.).—5 P.M. Mr. Waggott: Diseases of Accessory Sinuses. (Post-Graduate Course.)

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (Brompton).—4 P.M. Dr. Latham: The Early Diagnosis of Pulmonary Tuberculosis.

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Eccles: Surgical Anatomy.

**THURSDAY (7th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

**THE HOSPITAL FOR SICK CHILDREN** (Gt. Ormond-street, W.C.).—4 P.M. Mr. Fennell: Clinical Demonstration.

**CHARING-CROSS HOSPITAL.**—4 P.M. Dr. Green: Cases in the Wards. (Post-Graduate Course.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Edwards: Electrical Examination of the Rectum.

**FRIDAY (8th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. T. Collins: Clinique. (Eye).  
**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Therapeutics.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Office, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.

## The Bradshaw Lecture

ON

### PROGNOSIS IN RELATION TO DISEASE OF THE NERVOUS SYSTEM.

*Delivered before the Royal College of Physicians of London on Nov. 5th, 1901,*

By JUDSON S. BURY, M.D., F.R.C.P. LOND.,  
PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

MR. PRESIDENT,—Allow me to thank you for the great honour you have conferred upon me by asking me to deliver the Bradshaw Lecture this year, and allow me to express a wish that the value of my lecture were in any degree equal to my appreciation of the honour.

When we first enter upon the practice of medicine we are, perhaps, too apt to separate diseases from a prognostic point of view into the curable and the incurable—that is, to recognise one class of diseases in which complete recovery is the rule and another class in which the tendency is to a fatal issue or to only partial recovery. With increasing experience of the course and terminations of morbid processes we find ourselves less able to draw sharp distinctions between the ultimate results of different diseases. We meet with formidable disease which appears to have been caused by some simple ailment that we had regarded as being completely cured. For example, we attend an adult suffering from influenza. In a fortnight he appears to be quite well, but a year later he consults us for headache, nervousness, incapacity for work, and other symptoms which constitute the condition known as neurasthenia, and he says that he has never been the same man since the attack of influenza. On the other hand, if we study diseases that are regarded as incurable we are surprised to find that every now and then such a disease is apparently completely cured. Thus we occasionally see cases which present the classical symptoms of brain tumour in which, after a time of anxiety, a stationary stage is reached; the prognosis becomes more hopeful, and, as regards the prospect of mere existence, it may be very good. More rarely we see a child recover from symptoms which, rightly or wrongly, we regarded as indications of tuberculous meningitis. Such experiences tend to make us more cautious regarding the prognosis of ailments which usually recover, more open-minded in respect to those which, as a rule, pursue a downward path. We begin to believe (1) that illness, however slight, may leave behind it some weak spot which, after months or even years, may be attacked by a noxious agent and become the starting-point of chronic progressive disease; and (2) that severe organic disease is not always fatal; that sometimes the morbid process is arrested, and, in exceptional cases, even completely cured. A full consideration of the subject, indeed, shows us that an accurate prognosis of disease is well-nigh impossible, and that even an approximate forecast presents great difficulties which are perhaps more prominent in relation to diseases of the nervous system than to diseases affecting other parts of the body.

The problem before us may be stated as follows. A part of the nervous system—say, a nerve-cell—is attacked by a poison. The effect will depend partly upon the nature, the virulence, and the duration of the action of the poison, and partly upon the resistance offered by the cell. Both factors present infinite variations. If we think only of the resistance of the cell which depends on its condition at the time of attack we see that this condition is the result of all the influences that have been brought to bear on the cell during its birth, development, and existence—that is, of its inherited qualities and its environment past and present. Moreover, its resistance may be helped by agencies outside it; for example, the development of antitoxins. It may be lowered, owing to the cell being cut off, in consequence of its altered condition, from the full benefit of the sensory and other impulses which it normally receives from adjacent neurons. The resistance, too, may be modified by influences which the lesion has itself induced in other parts of the nervous system—as, for example, the inhibition of the functions of other centres. Furthermore, the direct effect of

No. 4080.

the changed condition of the cell on its surroundings, as on its axone or on the arborisations of neighbouring neurons, has to be taken into account before we can attempt to grasp the pathology of the situation. The results of such cell disturbance are manifested to our senses by what we call symptoms, and very often they are the only elements of the disease with which we are acquainted. Thus the condition known as hysteria is a mere collection of symptoms which may give us information as to the site, but none as to the nature, of the lesion. In other cases we know something of the attacking agent—as, for example, syphilis—and of the changes it produces in nerve-tissue, and then we can form a more complete diagnosis. But even in these cases it is usually far easier to make a regional than a pathological diagnosis, and this will continue to be the case until our knowledge of the causes of the disease has attained a firmer basis. It is, then, our ignorance of etiology and of general pathology in its broadest meaning which makes our diagnosis and our prognosis so often imperfect or erroneous. In the meantime it may be profitable to review our knowledge of some of the elements which, as I have indicated, are essential factors in the framing of a prognosis.

#### PROGNOSIS IN RELATION TO THE ATTACKING AGENT.

Our knowledge of the various agents that may set up disease is too limited to help us much in making a forecast of particular ailments. A clot in a cerebral vessel will rob a portion of brain of its blood-supply and thus lead to impairment or loss of functions, but from the symptoms presented to us we cannot determine whether the obstruction will be temporary or permanent. A blow on the head, insufficient in force to cause fracture of the skull or other gross lesion, may produce symptoms of concussion from which the patient slowly recovers, but we are unable to say that a cure is established, for a train of symptoms may begin to develop some time after the accident, symptoms which in some cases indicate a more or less permanent damage to cortical cells; while in other cases they point to the presence of a brain tumour. There is good evidence that irritation of sensory nerve-fibres may lead to muscular atrophy. Thus articular lesions are often quickly followed by wasting of the muscles that move the affected joint, and especially of its extensor muscles. In some cases the atrophy is persistent, and it may spread to other muscles of the limb. I believe that sometimes progressive muscular atrophy is initiated in a similar manner. For example, a policeman in a severe struggle with a maniacal patient strained some of the muscles of the right arm. Two or three weeks later he noticed that the limb was getting thin and weak, and in a few months the case was clearly one of chronic anterior poliomyelitis.

An absence of the secretion of the thyroid gland appears to be the cause of the impaired brain functions met with in cretinism and in myxoedema, while absence of the parathyroid secretion has probably something to do with the origin of exophthalmic goitre. Still we know but little regarding the resulting chemical changes which lead up to these diseases, nor can we say how far symptoms in other nervous maladies may depend on modifications in the quantity or the quality of gland secretions which enter the circulation. As to poisons, which may be regarded as the commonest causes of nervous disease, we are daily acquiring more knowledge. We know a good deal regarding the course of diseases produced by alcohol, lead, arsenic, and other poisons which are introduced into the body, and something of the effects caused by poisons which are the products of bacteria and which are produced within the body, such as the toxins of syphilis and tubercle. By analogy rather than by actual demonstration the nervous sequelæ of specific infectious diseases are attributed to the effects of the toxins of special micro-organisms. In the case of disseminated sclerosis, infantile paralysis, myelitis, and many other nervous affections, we assume that they, too, may be set up by poisons some of which might be derived from the products of over-fatigue, or of abnormal digestion in the alimentary canal, or from the perverted function of some other organ or tissue.

Two striking features may be noted regarding the effects of poisons—namely, their selective action and the immunity which is the direct result of their action. Immunity, however, is not known to occur in the case of poisons which are not of bacterial origin, with the exception of opium and tobacco. In the case of toxins both selective action and immunity play an important part in the prognosis of disease

and may now be briefly illustrated by reference to the nervous diseases produced by syphilis. The poison of syphilis shows a preference for the vascular structures at the base of the brain, for branches of the cerebral and spinal vessels, for the afferent conducting paths of the spinal cord, and for the cortical cells in the anterior part of the brain. Now, it is often stated that organic affections of the nervous system run a more favourable course when due to syphilis than when they are started by other agencies. The statement, if true, must be taken with considerable qualifications. When brain tissue is destroyed by the blocking of an artery it matters not whether the clot be of syphilitic or other origin; the result is permanent impairment of function. If brain tissue is damaged but not destroyed, then as much recovery may take place when the arterial obstruction is due to embolism from heart disease as when it is due to thrombosis from syphilitic endarteritis. But if there is only a narrowing of vessels there is reason to believe that the thickening is more amenable to treatment if syphilitic than if due to other forms of arterial sclerosis.

Exudation from syphilitic vessels may be removed by treatment, but it is impossible to say to what extent this will occur in any individual case. Moreover, there can be no doubt that absorption of exudations occurs in other specific infections, as, for example, in connexion with the inflammatory products which sometimes occur in the brain as a result of influenza, or in the cord in cases of myelitis of unknown toxic origin, for it is certain that occasionally well-marked symptoms of myelitis not due to syphilis entirely pass away. Two marked instances of such recovery have recently been under my care. Even if it be admitted that syphilitic exudations are more readily removed than are those which are not syphilitic, the admission is not opposed to a further statement—namely, that the prognosis of syphilis in relation to nervous diseases may, in respect to the final outcome, be worse than that of any other poison. One thing at least is certain—the germs of syphilis once introduced into the body are difficult to destroy. A syphilitic patient recovering from an attack of right hemiplegia may be seized with left hemiplegia. A syphilitic myelitis may develop some years after symptoms of cerebral syphilis, or a patient suffering from syphilitic meningo-myelitis may make a partial or complete recovery, and be adequately treated for a long time afterwards, and yet subsequently may have another serious breakdown in some part of his nervous system. In this respect syphilis presents a contrast to the acute specific fevers. For example, if the poison of measles sets up a disseminated myelitis and the patient recovers we are pretty confident that no subsequent nervous affection will develop as a result of the original infection. In syphilis, on the contrary, there appears to be an infinite capacity for future developments of its toxins. Some authorities have stated that if a person who has contracted syphilis is placed under proper treatment for a couple of years he may in the majority of cases be regarded as completely cured. My experience is opposed to such an opinion. It may be true that some persons are cured, but we cannot anticipate such a result. It does not follow because a person presents no symptoms for many years that he is cured. The germs of syphilis may lie hidden in his body, giving not the slightest indication of their deadly presence; and then after a period of 10 or even 20 years may suddenly revive, shatter his nervous system, and put an end to his life, after a few years of insanity or of a painful miserable existence. If this be the outlook for the future condition of the nervous system in the subjects of acquired syphilis, what is to be said of the prognosis when the poison is inherited? Here the outlook is equally uncertain and, if possible, even more gloomy, for the type of nervous syphilis in the child is a diffuse sclerosis of the cerebral cortex which arrests its growth, paralyses its highest functions, and slowly but surely leads to chronic progressive dementia.

Now, if we have to speak so cautiously about the course of diseases produced by a poison, the effects of which have been so carefully studied as those of syphilis, how much more caution is necessary in speaking of the action of poisons whose effects are so little known as those which we assume to be the exciting agents of disseminated sclerosis, of Landry's paralysis, and of many other forms of nervous disease. At the outset I alluded to influences, inhibitory or otherwise, which tend to modify the resistance of the part first attacked by an injurious agent. A consideration of such influences is of great interest, but I must pass them by in order to have time to make some remarks on the relation

of prognosis to the changes which are the result of these counteracting forces and to their outward expression by means of symptoms.

#### PROGNOSIS IN RELATION TO MORBID ANATOMY.

To what extent is the course of a nervous disease modified by the size, situation, and nature of the lesion present?

*Size.*—The mere size of a lesion appears to have but little influence on the progress of disease. A slowly-growing tumour in certain regions of the brain may reach a large size without giving rise to much disturbance of function; moreover, its development may be arrested, all the symptoms produced by it may pass away, and occasionally a partial recovery is established. On the other hand, a person who presents the group of symptoms which constitute Landry's paralysis, or the condition known as myasthenia gravis, may die within a few weeks or months, and no changes be found in the nervous system after the most careful microscopical examination. The terms "functional" and "organic" have been somewhat unfortunately used to separate diseases according to the presence or absence of visible changes. Now, visibility is a relative term; it depends on our eyesight and the powers of our microscopes, and, as regards nervous structures, to some extent on staining reagents, and, let it not be forgotten, on the thoroughness of our search. Hence with improved methods of investigating nerve tissue we may expect that the group of functional disorders will get smaller and smaller. If on grounds of convenience these terms be retained two points should be clearly recognised—namely: (1) the term "functional" ought to mean, not the absence of morbid changes, but only the absence of detectable changes; and (2) it ought not to be taken for granted that a disorder which has no known structural changes will run a more favourable course than one in which such changes are apparent. The lesions underlying paralysis agitans, exophthalmic goitre, epilepsy, and spasmodic torticollis are unknown to us, yet we cannot regard these diseases as curable. Death may result from a profound chemical disturbance of the atoms and molecules of nerve tissue which leaves no visible trace, and between such minute changes and a large lesion there must be every gradation in size.

*Situation.*—When the bulbar neurons which preside over the functions of respiration and deglutition are involved life is seriously endangered. When other cells and fibres are implicated the question of loss of function has to be considered rather than that of any immediate danger to life. It may be accepted as a general law that, other things being equal, lesions of the peripheral nerves are more quickly and completely recovered from than lesions of the central nervous system, and that lesions of the brain, at least as regards the degree to which function is impaired, are less serious than those of the cord. Thus the brain may be the seat of relatively large lesions without any definite symptoms being produced, while, owing to the small space transversely occupied by the centres and conducting paths in the cord, a comparatively slight lesion may injure it irretrievably. The situation of the lesion influences the degree to which impaired or lost function may be compensated for by the action of healthy parts of the nervous system, and, therefore, it has a definite relation to prognosis. For example, in hemiplegia the motor power of the leg is more readily restored than that of the arm, because the motor neurons of the legs are more intimately connected by association fibres in the cerebral and spinal commissural tracts than are those of the arm. In infantile paralysis the functions of the cells in the anterior horns, which are destroyed at a certain level, may be taken up by healthy cells at a higher or lower level. The principle of compensation also may be seen in cases of muscular atrophy, where a muscle may hypertrophy in fulfilling the function of its atrophic neighbour. It explains also to some extent the more favourable prognosis in affections of the sensory, as compared with those of the motor, mechanism, for, as is well known, the conduction of motor impulses is much more restricted to definite tracts than is that of sensory impulses. As regards the central nervous system then, restoration of function may be said to be due either to the recovery of nerve tissue which is only partially damaged or to the taking up by adjacent or distant structures of the functions that are lost, for there is no satisfactory evidence, and I have Dr. F. W. Mott's authority in support of the statement, that nerve-cells or fibres in the brain or cord which are completely destroyed can ever be replaced by new cells or fibres. Dr. Mott informs me that

he has frequently in degenerating tissues seen attempts at mitosis of the nucleus of a cell, but he has never seen this proceed to the development of a new cell.

With regard to the pathological significance of lesions in different parts of a nerve-cell the observations of Marinesco, Lugaro, and other investigators are of great interest. Lugaro<sup>1</sup> states that "lesions of the chromatic part are the first to appear in all cases in which the harmful action does not act suddenly and with such energy as to paralyse function; that they are in every case reparable, even when very grave, provided that the other parts of the cell have not suffered serious damage. It is very doubtful, however, if lesions of the achromatic part can be repaired, more especially since they very often appear contemporaneously with lesions of the nucleus, the integrity of which is indispensable for the conservation of the cell. He points out that there is no exact and constant relation between lesions of the chromatic part and functional disturbance, that the functional activity of the cell can continue even when the chromatic part is injured, and that this part does not possess structural arrangements necessary for the fulfilment of its function, which depends therefore upon chemical composition and not upon morphological disposition. Within certain limits of structural alteration function can remain intact, and will not exhibit disturbance with certainty except in cases of grave alteration, when the nutritive alteration is also grave. On the other hand, function will be entirely suppressed when the structural dispositions of the achromatic part, which seem more strictly related to the nervous conduction, are altered, or when they are suddenly affected by energetic chemical action."

*The nature of the lesion.*—If we could see the changes which occur at the onset of a morbid process, are they different in different diseases? Take a well-marked case of neurasthenia where a man in the prime of life begins to lose his mental capacity; his memory fails, he loses interest in everything; he cannot bring himself to do simple things, such as the writing of a letter. We assume that his cortical cells are deranged. In what way are they altered? Is the kind of change different to that which constitutes the initial stage, say, of general paralysis? In both diseases we have reason to believe that the cause is a toxin; in general paralysis this is usually of syphilitic origin; in neurasthenia its origin is not known. If the very earliest changes in the cortical cells of the two diseases were visible, would they be like or unlike? If like, we must assume that different poisons may at first produce the same results; and then, if the changes in the one case are progressive and lead to degeneration of the cells, which is represented by the symptoms of general paralysis, while in the case of neurasthenia they are more or less stationary, we should be at a loss for an explanation. Probably, if we found similar identity in the initial morbid changes of other diseases we should be disposed to believe that variations in progress might be due to variations in the dose of poisons; that a case of neurasthenia, for example, which had remained stationary for some time might, if the dose of its poison were increased, develop into one of general paralysis; in other words, that one disease might pass into another. This is a fascinating speculation, and is to some extent supported by the transitional clinical forms that are met with between well-marked types of different diseases. But, for my own part, I prefer to believe that each poison has its own point of attack and that the earliest change of each disease has its own peculiarities, minute enough, no doubt, and still invisible to our present methods, but which, if visible and thoroughly recognised, would enable us to diagnose the condition and to foretell its probable developments. This view receives support from the investigations of Lugaro<sup>2</sup> whom I have already quoted. He says: "The study of subacute intoxication has shown us that while the primary lesions of the nerve-cells have common features there are not wanting in them particular characters by which we can more or less completely distinguish one intoxication from another. The alterations that result from chronic intoxications present, according to Nissl, a remarkable uniformity both as a whole and individually. This fact, I believe, may be explained by the circumstance that the toxic action is complicated by autotoxic actions resulting from secondary disturbances of metabolism

and from alterations of the other viscera that reciprocally exercise an influence on the brain. These secondary disturbances, relatively uniform, must tend to mask the primary action, cancelling the original diversity of the picture produced by the various agents. The action of general and local infections of the nervous system has a very great analogy to that of the intoxications. This we can easily understand if we consider the greater importance of the indirect and general action exercised by the micro-organisms through their toxins in comparison with their direct and local action."

Are there any changes which immediately precede the minute ones in nerve cells which I have assumed to constitute the histological basis of the earliest symptoms in nervous diseases? The toxic material passes in the blood along the walls of a vessel; does it attack the nerve cell only or does it first attack the delicate and active endothelial cells lining the vessel? It is possible that some toxins may first attack the nerve cell and have their action limited to it, at least for a time, but histological evidence speaks strongly in favour of a previous, or at any rate of an associated, vascular lesion. Undoubtedly the prevalence of vascular lesions is the most striking thing in the morbid anatomy of cord and brain diseases. In all forms of myelitis, in disseminated sclerosis, and in poliomyelitis the spots of the disease are closely related to the distribution of blood-vessels, which may contain thrombi, have their coats thickened and their perivascular lymph sheaths crowded with round cells. These changes strongly suggest the action of some irritant on the endothelial lining of the vessel, which leads to an increased flow of lymph and leucocytes into the perivascular tissues and thus initiates the earliest nerve lesions. Apart, too, from visible vascular lesions, an irritant may set up spasm of muscle in the wall of an artery, for it seems probable that vaso-motor spasms may play an important part in the symptomatology, not only of organic disease, but also of hysteria, neurasthenia, headache, and many other functional affections.

#### PROGNOSIS IN RELATION TO SYMPTOMS.

We have seen that the influences at work in the production of disease and its effects are manifold, for in addition to the morbid changes which occur in the part attacked, which present infinite variations owing to variations in the nature and strength of the attack and of the resistance offered to it, we have to consider the changes which may be set up at a distance from the lesion, changes which, whether temporary or permanent, may cause certain inhibitory or accelerating influences to be exerted on the functions of various parts of the nervous system. If, then, the influences at work and their effects are so complicated, how shall we adequately interpret the results? The only manifestations to us are symptoms, and these depend, not on all, but only on some of the results of the disease. Our difficulties are still further increased by the fact that symptoms vary in different persons quite apart from the severity, distribution, and nature of the lesion. For example, with the same amount of irritation of sensory fibres the perception of pain in one person is extreme, in another very slight. Thus, one has watched the course of painless intrathoracic aneurysms and of pyloric cancers, and has felt convinced that the mere locality of the lesion was not sufficient in itself to account for the absence of pain. Again, one has seen cases of cerebral tumour in which headache was but slight and certainly far from constant. Without stopping to find reasons for such idiosyncrasy one may bear it in mind as a partial explanation of variations in other symptoms, objective as well as subjective; thus, I do not think that morbid anatomy always explains why paralysis is profound in one person, moderate or only slight in degree in another, or why the degree of muscular spasm varies so much in affections of the upper neuron.

As an example of want of correlation between symptoms and morbid anatomy the following case of glioma of the cord is worthy of record.

CASE 1.—A man, aged 24 years, was admitted under my care at the Manchester Royal Infirmary last June, complaining of weakness of the right arm. He stated that he first noticed the weakness on waking one morning, about three months before admission, and that during the last four weeks his neck had felt stiff and sore. On examination, all the muscles of the right arm were weak and wasted; he could feebly flex the wrist and fingers and feebly supinate and pronate the hand, but he was unable to extend the wrist

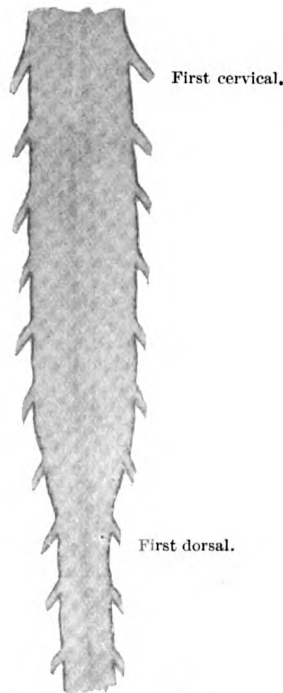

<sup>1</sup> Rivista di Patologia Nervosa e Mentale, 1899, quoted by Ford Robertson in his Text-book of Pathology in Relation to Mental Disease.  
<sup>2</sup> Loc. cit.

or to perform any movements at the elbow or shoulder. The power of the left arm was good, with the exception of flexion of the hand and fingers, which was feeble. As regards cutaneous sensibility he could feel the slightest touch, and everywhere could distinguish between the head and the point of a pin. Sometimes the pain produced by a pin-prick seemed to last longer than normal, and sometimes he multiplied the number of points of contact; occasionally he appeared unable to distinguish between a hot and a cold test-tube when applied to the right arm. The head was inclined towards the left shoulder; he was unable to move it back beyond the vertical position. He could turn his chin better towards the left than the right side; this was due to pain in the neck rather than to muscular weakness. The fifth and sixth cervical spines were tender to pressure, but only to a slight degree; and the skin of the right side of the neck was a little more tender to pressure than that of the left side. There was no hyperæsthesia elsewhere. Both knee-jerks were present; the right was feebler than normal. On June 22nd the patient was shown at a meeting of the Neurological Society held in Manchester, and various opinions were expressed as to the nature of the lesion. At this time sensation was practically normal, and the neck tenderness was very slight; there was indeed no evidence that any of the cervical roots were involved. Most of those who examined the case regarded it as one of anterior poliomyelitis; one or two members of the society suggested the possibility of a new growth involving the cord. At the end of June weakness of the left arm became more marked, and the first dorsal inter-

weaker than before the operation. The retention of urine continued. On July 11th the patient was decidedly worse and almost completely paralysed. His face was flushed and his breathing was entirely, or almost entirely, diaphragmatic. Both arms were completely paralysed; the legs could be slightly moved by a voluntary effort, but such movement amounted to little more than a twitch. A most careful examination failed to indicate any trace of anaesthesia or of hyperæsthesia. The knee-jerks were absent. The breathing became more and more embarrassed and he died in the afternoon.

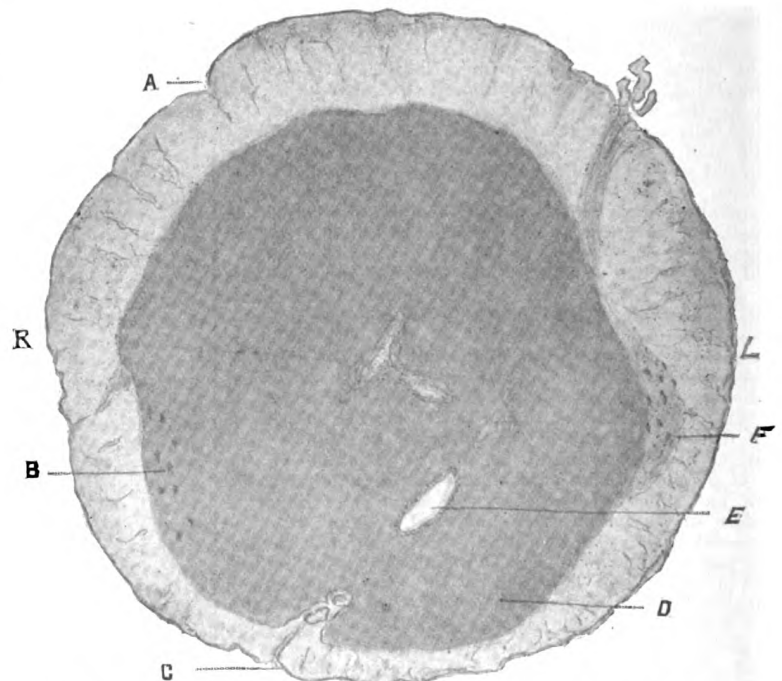

For the following pathological report I am indebted to Dr. F. C. Moore: "Body that of a tall, well-nourished, muscular man. Marked atrophy of the muscles of the right arm. The intra-thoracic and abdominal organs were apparently normal. The brain also presented a healthy appearance. The cervical portion of the spinal cord was greatly enlarged in its whole extent (Fig. 1). On section this was found to be due to the presence of an elongated ovoid mass of new growth which extended from the second segment to the commencement of the dorsal cord. At the upper and lower ends the mass of new growth gradually became thinner and terminated in a bent cone. To the naked eye the cut surface of the tumour presented a uniform greyish, semi-translucent appearance; peripherally it was invested by a thin layer of white matter. A section through the middle region of the tumour showed under the microscope that the new-formed tissue occupied the greater portion of the transverse area; it was completely invested by a narrow zone, varying in thickness, of nervy tissue. The growth approached nearer to the anterior than to

osseous muscle was distinctly wasted. A blister formed on the palmar surface of the third finger, and a little later another developed on the dorsal aspect of the middle finger. After two or three consultations with Mr. Thorburn it was decided that a growth could not be excluded, and on July 9th Mr. Thorburn performed laminectomy. No growth was found outside the dura, nor was there any indication of bone disease. On opening the dura a great deal of spinal fluid escaped, but no lesion was discovered. After the operation the patient was quite comfortable and his breathing natural. He was unable to pass urine, which had to be withdrawn by the catheter. The evening temperature was 100° F. His condition remained favourable till the following evening, when his temperature rose to 103° and his breathing became hurried and distressed. The left arm was now much

the posterior surface of the cord, and nearer to the right than to the left side. In structure it consisted of a matrix of interlacing fine fibres containing a considerable number of cells, many of which were large and multinuclear; others were small and obviously belonged to the neuroglia. There were some scattered capillary vessels. The new growth was apparently a neuroglioma and had probably originated in the tissue round the central canal. The periphery of the tumour was well defined and sharply delimited from the investing nerve tissues. On the left side the cornua— anterior and posterior—of grey matter were drawn out antero-posteriorly and compressed laterally (Fig. 2). In structure they appeared quite normal, the large ganglion cells being unchanged. The left lateral column of white matter was compressed, but its area was probably not

diminished in size and its component fibres were unaltered. The left posterior column, also altered in shape, was not much diminished in area and was not degenerated. The anterior column was greatly attenuated and was represented by a narrow zone of fibres compressed between the bulging tumour and the pia arachnoid. On the right side of the tumour the grey matter was represented by a few scattered ganglion cells which were situated in the outer zone of the tumour. These few cells were normal in appearance. The lateral and posterior columns, though deformed, were apparently but little altered; probably, however, there was some destruction of their fibres owing to the encroachment of the tumour."

In the next place we must remember what Dr. Hughlings Jackson has so justly emphasised—namely, that symptoms are due as much to normal physiological functional activity imperfectly applied as to the actual loss of function occasioned by the lesion; in other words, that symptoms result, not only from the changes at the seat of the lesion, but also from the normal or perverted action of healthy neurons, as an indirect effect of the lesion. Thus the foot deformities met with in infantile paralysis are partly due to the unopposed action of healthy muscles, while the exaggerated movements of a tabetic patient depend to some extent on lowered tonus of the muscles through a cutting-off of sensory impulses from the motor neurons. An analogous phenomenon is the muscular atrophy which follows articular inflammation or that which occasionally attacks a hemiplegic limb. These effects probably result from inhibition of the functions of nerve cells. As another instance of inhibition may be mentioned cases of granular kidney unattended by dropsy in which when an attack of hemiplegia occurs the paralysed leg becomes cedematous. Furthermore, we may observe that symptoms represent both active and passive or arrested phases of disease. For example, we see two cases of what are called birth palsies. The patients have reached the same age and both exhibit spastic limbs and a certain degree of dementia. In one case the condition has been stationary for many years; in the other convulsive attacks have occurred every week or every month since infancy, and the mental functions have gradually deteriorated. In both cases there is permanent damage to cortical cells; in the first case this is all, and the physical health and the duration of life are not seriously imperilled; certain functions are lost by the cutting off of a part of the brain, as the functions of a limb are lost by its amputation. But in the second case living cortical cells are disordered and the manifestations of the disorder indicate the probability of a downward course. It is, then, the symptoms which testify to active phases of disease which, for purposes of prognosis, require to be carefully studied. They have a natural history of their own which calls for independent investigation and which is not as yet adequately explained by morbid anatomy. Very often, indeed, a group of symptoms is the only part of the disease known to us. To this we give a name and are said to have made a diagnosis. Thus to one group of symptoms we give the name of tetany, to another paralysis agitans, and to a third epilepsy. In epilepsy we assume that the cells of the cerebral cortex are at fault, but in tetany and paralysis agitans we know neither the site nor the nature of the lesion. In such cases as these accuracy of prognosis will vary with accuracy of observation in regard to symptoms. We require to have a thorough acquaintance first with types and, secondly, with aberrant forms. In short, we ought to know the natural history of the disease as revealed to us by its symptomatology. In these days, when the chemistry of nerve tissue and the pathology of the neuron are so keenly investigated, we may ask, Is the same ardour evinced by clinicians in the study of symptoms? Do we accurately note day by day the variations in the symptoms of cases, say, of myelitis or of locomotor ataxy? When we have done so we have been astonished to find how frequently slight variations may be detected even when the case is to all appearances a chronic one. We talk of the influence of the mind on the body and of the body on the mind as if their mutual relationships were well understood, but do we understand the meaning of the trophic lesions so often met with in the insane or the temporary improvements which sometimes occur in the subjects of organic disease who visit such places as Lourdes and Holywell? In one case of transverse myelitis known to me a man who was unable to walk bathed at Holywell. After the dip he was able to walk and the

next day he walked without crutches. The improvement lasted for 10 days and then the paralysis returned, when he came under the care of Dr. J. Dreschfeld at the Manchester Royal Infirmary. Such improvement is not more wonderful than the temporary improvement in insanity which follows the application of a blister to the neck. On the other hand, can we distinguish between the mental phenomena of visceral disease? For example, can we speak accurately regarding the various states of mental depression seen in stomach affections or differentiate the physical symptoms which occur in the later phases of lung and heart diseases? The more closely we study symptomatology the more we are struck by its complexity and by the necessity for greater care in making our observations and in forming our judgments. As already indicated, diseases of the nervous system may be divided into two groups, according to the presence or absence of visible morbid changes. A disease belonging to the group which is represented to us by symptoms only may have its course foretold as well as one of which the morbid anatomy is well known. A correct prognosis of any particular case of paralysis agitans is neither more difficult nor more easy to make than one of disseminated sclerosis. Prognosis depends less on our knowledge of pathology than on the accuracy of our experience with regard to symptomatology. But sometimes we observe a group of symptoms or a single symptom which, although it may give us a clue as to the part of the nervous system affected, does not enable us to make a diagnosis in any acceptance of the word.

Of isolated symptoms numbness is one of the most common. The subjective sensation may or may not be associated with slight anæsthesia. What is its significance? A married lady consulted me four years ago for numbness of the left arm and hand. On examination, I found slight tenderness over the fifth cervical spine and slight relative anæsthesia down the outer side of the arm. There was no hyperæsthesia and there were no other symptoms whatever. She was not hysterical and there was no evidence of gout, dyspepsia, or any other possible cause. She came again to me the other day; the symptoms were unaltered and she said that, in spite of massage and other treatment, the numbness had been present every day during the four years; in other respects she was quite well. I have seen several cases of numbness and slight anæsthesia, often of root distribution, sometimes in connexion with dyspepsia—as in one case where the distribution was along the inner aspects of both arms, in which the symptoms passed away after a few weeks. In the case just related there is no reason to suspect serious disease, but we cannot exclude it, we cannot deny the possibility that the agent at work is a pernicious one, which in another person might have led to a disseminated myelitis or other serious disease, instead of its action being checked as in the above case. The persistence of the numbness, especially as it is a sensory symptom, is remarkable, but perhaps not more so than the persistence of some cases of neurasthenia and of other so-called functional affections.

In contrast to the above case the following is of much interest.

CASE 2.—In December, 1893, a young woman consulted me for numbness of the feet and the left side of the face. Her manner was somewhat hysterical and I was unable to find any objective signs of disease. The numbness passed off in two or three weeks. Eighteen months later she consulted me again; she complained of much weakness and looked ill and thin, but the only definite evidence of disease was a distinct exaggeration of the wrist-jerks and knee-jerks. This symptom made me suspect the onset of disseminated sclerosis, and the other well-marked symptoms of this malady gradually developed, and she died three years later. In this case is the numbness to be regarded as an early symptom of the disease which ultimately declared itself in an unmistakable manner? Was it the result of exudations in the sensory path set up by the toxin of sclerosis or was it the result of some other cause? I am inclined to take the former view, although, speaking generally, I do not think that numbness *per se* is a symptom which is commonly of much significance, for nerve-tissue is often so unstable that a very slight alteration in the quantity or the quality of its blood-supply may lead to interference with sensory conduction. At the same time, numbness does indicate a disorder of the sensory path and therefore its presence suggests the necessity of making repeated careful examinations of the patient who suffers from it.

The first case of persistent numbness shows that a definite lesion of the fifth cervical root had existed for four years. Obviously the lesion was a very slight one; it might be the result of the constant action of some poison which showed a preference for that particular region, for of the curious ways in which poisons locate themselves there appears to be no end; while owing to our imperfect methods of producing elimination the local toxic effects may persist indefinitely. Indeed, it seems reasonable to suppose that almost any variety of cell or fibre may be selected by a poison as its seat of attack. Thus the poison of tetanus selects the motor nucleus of the fifth cranial nerve, nicotine picks out the optic nerves, lead some of the branches of the musculo-spinal nerves, while the toxin of influenza may attack almost any part of the nervous system. Reference to our knowledge of influenza would alone justify the assumption which I have made regarding the unlimited modes of selection exhibited by poisons in different cases. Paralysis of some of the eye muscles may be mentioned as another isolated symptom that is often difficult to understand. Some cases are met with apart from syphilis or influenza or other ascertainable cause.

CASE 3.—Last February, a man, aged 37 years, consulted me for double vision and general debility. He said that the symptom, "seeing double," was first noticed on getting up one morning, about a week previously; it was preceded by numbness of the fingers for two or three days. I found complete paralysis of the right external rectus, partial paralysis of the left internal rectus, and slight impairment of the movements of the right facial muscles; no other symptoms were present. The man was a clerk and had felt over-tired for some time. No other morbid antecedent than overwork could be discovered. I saw him again in March and in April, and on each occasion the symptoms were less marked. In May—that is, three months from the onset of his disability—no paralysis could be detected. The treatment consisted in the administration of strychnine and potassium iodide and in rest from work.

The significance of a numbness or a limited paralysis is hard to determine and a cautious prognosis must of necessity be given. Even if we knew the exact nature of the toxin we could not foretell the issue with certainty. Probably in a large number of what are called functional paralyses the minute lesions are quite different from those which constitute the initial stage of a serious disease such as disseminated sclerosis; but we must not regard complete recovery as a differential test; surely it is reasonable to believe that the minute initial changes of a serious disease may be removed and that no future developments will take place. I think that evidence in support of such a belief is afforded as we shall presently mention by a study of the course of serious organic disease. I would contend that the constant use of the term "functional" has hindered the advance of knowledge. Its implication that the changes at present invisible to us are of different nature to those at the onset of serious disease has alone sufficed to limit our view and to prevent our thoughts taking the direction just indicated. Similar remarks might be made regarding the use of the word "hysteria"; a discussion on this subject, however, is somewhat outside my present topic. It must suffice to remind you of the investigations of Buzzard, Bastian, and others, which have done so much to narrow the boundaries of hysteria, and to state my belief that increasing knowledge of pathology will tend to reduce its limits still further. Prolonged vascular spasm or some other lesion must underlie a profound anaesthesia or a contraction of the visual fields. What is meant by calling these phenomena hysterical? In some cases they persist for years, even throughout life, and when they disappear have we adequate knowledge of the subsequent nervous history of the patient? With regard to motor phenomena, such an authority as Charcot has stated that persistent hysterical contractures, after lasting for many years, may be attended with structural changes in the spinal cord; in one case he found a lateral sclerosis, which apparently he regards as a direct outcome of changes started by the hysterical contracture. I find it much easier to believe that from the very first there were minute definite changes to which any hysterical or psychical manifestations were secondary. Commonly enough, such manifestations are met with in association with and frequently overshadowing symptoms indicating organic disease. They are often misleading and tend to make us overlook the significance of a definite objective sign such as paralysis of a group of muscles. In my experience it is rare to meet with psychical paralysis, and when it occurs it is

weakness of a complicated movement rather than of individual muscles. Thus the power to stand or walk may be lost when the movements of the legs in bed are normally performed. We are told that such a patient is not shamming but is suffering from a genuine disease, hysteria; it is always difficult, however, to exclude the absence of real effort on the part of the patient.

I will now briefly relate the clinical histories of three remarkable cases of recovery from symptoms which indicated serious disease. In the first case hysterical manifestations were present, in the other cases they were absent.

CASE 4.—The patient, a girl, aged 22 years, was under my care at the Manchester Royal Infirmary from October, 1893, to May, 1894. There was a history of headache, of impaired vision, and of occasional partial losses of consciousness. On admission she was dull, apathetic, and hysterical. There was partial paralysis of the right arm and leg, and at times of the right side of the face. Optic neuritis was well marked, she suffered from constant headache, and pain was caused by pressing on the occiput and neck. At first cutaneous sensibility was normal, but at a later period there was partial anaesthesia down the left side; then paralysis of the right external rectus was noticed. Subsequently the hemianæsthesia disappeared and the left limbs became weak, but they were not so paralysed as the right limbs, which at one time seemed to be deprived of all power of voluntary movement. Optic atrophy succeeded the neuritis, and the girl became absolutely blind with the left eye and partially blind with the right eye. During this time the right knee-jerk was exaggerated and the left one was very feeble; there was no ankle clonus. In December—that is, three months after admission—double ptosis developed. In January the ptosis had disappeared as well as the paralysis of the right external rectus. In February she passed every night in a semi-conscious, delirious state. In March she was able to walk with assistance in a feeble manner. On leaving the hospital in May she went to stay with friends in London. Towards the end of 1894 Dr. C. E. Beevor wrote to me saying that she was an inmate of the National Hospital for the Paralysed and Epileptic in Queen-square. In reply to his inquiries I gave him the history of the case and said that if it had not been for the optic neuritis and the affection of the right sixth nerve I should have been inclined to regard the case as a so-called functional one. A few months later he wrote again, saying that her symptoms had become worse; vomiting and headache were severe, there was marked staggering in walking, double ptosis was present, and there was anaesthesia down the right side. Dr. Beevor thought that there was a tumour in the neighbourhood of the left occipital lobe and after a consultation with Mr. C. A. Ballance it was decided to trephine. Mr. Ballance operated and found nothing abnormal. The patient made a good recovery from the operation; the headache and vomiting ceased; the ptosis, however, and a loss of conjugate movement of both eyes to the left persisted, as also did the right hemianæsthesia. A few weeks later she became maniacal. But what was most interesting, wrote Dr. Beevor, her ptosis, conjugate paralysis, and hemianæsthesia all disappeared and her sight returned, so that she could read small print. "I am now inclined to agree with you that, except for the optic neuritis followed by atrophy, the case looks very like a functional one." The girl was sent to the Bethlem Hospital. Some 18 months later I was surprised to receive a well-written letter from her in which she stated that she was quite well with one exception—namely, that her eyes became painful after reading a few words.

Time will not permit me to comment on this remarkable case, but I would repeat that definite objective signs of brain disease were observed both in Manchester and in London, that they entirely passed away, and that the patient regained her health and was able to resume her occupation.

CASE 5.—This case, which I saw with Dr. J. Robinson of Dunscair in February, 1897, was one of spastic paralysis in a young woman, aged 22 years. She had suffered from numbness and weakness in the legs for three months before I saw her. Her gait was feeble and spastic in character. The flexor movements at the hip, knee, and ankle were weaker than normal; the extensor movements were fairly strong. The legs were very rigid; the knee-jerk was much exaggerated, and there was well-marked ankle clonus. The right abdominal reflexes were present, the left could not be obtained; the plantar reflex was absent. The cutaneous sensibility was unimpaired; micturition was somewhat

delayed. After a full consideration of the case I concluded that it was not one of hysteria and that the diagnosis rested between a dorsal myelitis and disseminated sclerosis, the latter being by far the most likely. The patient made a good recovery and Dr. Robinson informed me the other day that she was still quite well.

Is this an instance of mistaken diagnosis or one of recovery from serious disease? Let me insist on the character of the ankle clonus. It was well marked and quite different from the feeble loose variety met with in hysterical subjects, and with experience of other similar cases I am convinced that paralysis with a true foot clonus, apart from hysterical contracture, is occasionally recovered from. Dr. Buzzard has recorded cases in which apparent recovery from disseminated sclerosis has lasted four or five years; hence, it is not impossible that the patient referred to, who has been free from symptoms for nearly four years, is not entirely out of danger. As to the absence of the plantar reflex I have observed its occurrence in other cases of disseminated sclerosis. In one case which I reported some years ago the reflex was absent till towards the termination of the disease, and although I recognise the importance of the extensor response as an indication of affections of the upper neuron I do not regard it as a pathognomonic sign.

CASE 6.—This case was one of atrophic paralysis affecting a girl, aged nine years, whom I examined in October, 1895. Both feet were dropped and all the muscles on the front of the legs were paralysed and wasted. The knee-jerks were absent and sensation was normal; there was no affection of the bladder or of the rectum. A careful examination of the spine revealed nothing abnormal. The diagnosis seemed to rest between acute anterior poliomyelitis and a motor type of multiple neuritis. I considered the former diagnosis the more probable of the two and gave a cautious prognosis and prescribed massage and other local stimulating treatment. In a year's time the muscles had almost completely recovered their normal bulk and power. In response to a letter she came to see me last August, just six years from the onset of the disease. The girl had a robust appearance and her legs were quite healthy and strong. She told me that occasionally she walked rather clumsily and that she was subject to cold feet. The right knee-jerk was normal and the left was a little exaggerated. These symptoms seemed to support the original diagnosis and I am inclined to regard the case as an instance of recovery from acute anterior poliomyelitis.

I will now leave cases of doubtful nature in order to have time to consider the course of diseases in which the diagnosis is certain and where there can be no doubt that the symptoms are associated with obvious structural changes.

CASE 7.—Some time ago I saw a child, aged four years, in the later stages of tuberculous meningitis, who suddenly passed from a state of deep coma to apparent convalescence; for a few hours he was bright, spoke to his mother, and played with his toys and then relapsed into fatal unconsciousness. Such fallacious improvement in this disease is well known and would not deceive the skilled observer. It is worth noting, because it seems to indicate that the freely circulating toxin which produces the coma may have its effects temporarily arrested by an antitoxin, or in some other way, and taken in conjunction with exceptional cases of recovery from tuberculous meningitis it gives rise to a hope that some day an antitoxin may be discovered which will counteract the effects of the poison.

The next case I would refer to was seen by Dr. Dreschfeld and Dr. Little and was diagnosed acute disseminated myelitis after measles.

CASE 8.—The patient was a young woman, aged 18 years, who the day after taking a cold bath broke out with the rash of measles. Whilst recovering from the attack of measles she complained of intense headache, of weakness of the legs, and of pain in the back. It was found that she had optic neuritis, and in a few days she became totally blind. The blindness was followed by paralysis, first of the legs and then of the arm; their cutaneous sensibility was also markedly impaired. There was retention of urine, with occasional incontinence. Within a month from the onset of measles all four limbs were completely paralysed. A fortnight later motor power began to return and in about four months the girl was quite well.

A study of the course of chronic nervous diseases such as disseminated sclerosis, locomotor ataxy, general paralysis, and myelitis is also full of interest in connexion with our present subject. It teaches us that the downward progress, which unfortunately characterises the majority of cases, is

by no means made by a constant succession of regular steps. On the contrary, it presents a most irregular course, of which the variations are infinite both in kind and in time of succession. Arrest of a chronic disease may occur at any stage; and while, as a rule, it is only temporary, it may be permanent. We are impressed, not only with the rare complete recoveries which may occur, but with the stationary periods, with the periods of marked improvement, and with the disappearance of individual symptoms, and their replacement sooner or later by others of the same or different kind. These points have been so ably illustrated by Dr. Buzzard in his studies on disseminated sclerosis that I need not further refer to that disease except to state that I could give examples from cases of my own of the various phases he describes and of the risks to diagnosis from the presence of hysterical manifestations to which he draws such just attention.

The clinical histories of locomotor ataxy and general paralysis are prolific in instances of arrested progress and of alternating periods of improvement and breakdowns. Sometimes, as in the following case, prolonged improvement or apparent recovery may be followed by symptoms almost malignant in their severity and rapidity of progress.

CASE 9.—The patient, a man, aged 27 years, consulted me in August, 1891, and was subsequently seen by Sir Thomas Barlow. When first seen he had definite ataxia, shooting pains in the legs, delayed sensation, delayed micturition, and the knee-jerk was absent. Some of these symptoms subsided, especially the bladder disturbance. He went to Aix-la-Chapelle and was much benefited by the treatment. In September, 1892, he paid a second visit to Aix, and there was still further improvement. He was married in December and continued to improve steadily. In May, 1893—that is, nearly two years after I first saw him—he wrote as follows: "I have regained my power of work and no longer experience extreme fatigue or distressing symptoms of any kind. My gait in walking is practically normal and I can daily walk any distance with as little exertion as before the complaint overtook me. The only remaining symptoms I notice are anaesthesia in the toes and some clumsiness in running movements, which, however, is much less when the muscles are fresh than when they are tired. The knee-jerk is still absent." A few months later, however, fresh symptoms developed—namely, oedema of the ankles and some small perforating ulcers. He was sent to undergo Erb's treatment at Heidelberg. This did not answer at all; he had a succession of bad arthropathies affecting the hips, the knees, and the shoulders. A little later symptoms of general paralysis set in rather abruptly and he was sent to an asylum.

Additional interest is attached to this case owing to its etiology. It is certain that the patient had not acquired syphilis in the ordinary way; he had a protracted illness after vaccination in infancy, which the medical man who vaccinated him regarded as due to inoculated syphilis.

Similar varying phases characterise the progress of general paralysis.

CASE 10.—A medical man suffered from well-marked symptoms of this disease and his friends were advised to sell his practice. They did so. Subsequently he recovered to such an extent that he appeared to be quite well. He married, and remained in what seemed to be in good health for about a year; then he suddenly broke down with aggravated symptoms of general paralysis and died shortly after.

What is the pathology of these variations in progress? I would submit that they support the view of a general toxic condition rather than that which has recently been so ably advocated by Dr. Mott—namely, that in tabes and general paralysis the syphilitic poison has so lowered the vitality of nerve elements that they undergo a primary and progressive decay. Let me again observe that the course of these diseases is not steadily progressive, that a subsidence of symptoms is followed by fresh outbursts, and that apparent recovery is often suddenly interrupted by the development of acute symptoms in various parts of the body. Such fluctuations remind one in a way of the temperature chart of a prolonged case of enteric fever in which at irregular intervals a series of high temperatures alternates with a series of low ones, the high curve corresponding to a fresh development of toxins, the low curve corresponding to abatement of their action. It is difficult to understand how the ups and downs which are such marked features in the clinical history of chronic nervous diseases can be explained

on the hypothesis of primary progressive degeneration of neurons owing to exhaustion of their specific vital energy and apart from the direct action of toxins circulating in the blood.

#### PROGNOSIS IN RELATION TO TREATMENT.

If I am right in assuming that a poison is the most common exciting cause of diseases of the nervous system, prognosis will vary with knowledge of the proper treatment for elimination of the poison and of the effects produced by it. But in most cases we know neither the nature of the poison nor the manner in which it enters the circulation, hence treatment is purely empirical and often fails. When we do know what the poison is and how it is introduced into the blood, as in the case of lead, we can stop any further introduction of the poison and then try to eliminate what is already present. Our methods of elimination, however, are still too crude for the purpose. We may employ massage and baths, administer purgatives and alteratives, and place the patient under the best hygienic conditions, often without producing any immediate result, witness the persistence of some cases of peripheral neuritis or neuræsthenia in spite of the most energetic treatment and our inability to stop the progress of an early myelitis. In addition to remedies for the elimination of poisons we want others to aid us in counteracting their effects, and here we must hope for fresh discoveries regarding the effects of glandular extracts and the nature of toxins and their antitoxins. In this connexion the influence of one disease upon another is worthy of renewed investigation. Two examples may be mentioned. A boy with whooping-cough was attacked with most severe urticaria; the whooping-cough quickly subsided. A man whilst suffering from severe neuralgia on the right side of the neck had an attack of bronchitis. Its onset was associated with a sudden disappearance of the neuralgia.

The possibility that a second attack of the same disease may have a beneficial effect on the symptoms left by a first attack is suggested by a case which was recently under the care of Dr. Dreschfeld. A man whilst suffering from influenza began to show symptoms of grave mental disturbance. He talked incoherently, was dull and apathetic, and passed his excreta into the bed. In a few weeks he was sufficiently recovered to take a holiday. Two months later he resumed his business, but his mental vigour was much less than before his illness. Six months after the first attack he had another attack of influenza and was very much afraid that his former symptoms would return; but, to the astonishment of himself, his friends, and his medical attendant, he made a rapid recovery, lost all his old symptoms, and regained complete health, both mental and physical. We have, further, to study the influence of one part of the nervous system upon another part. Thus, a knowledge of the value of sensory impulses in maintaining the proper nutrition of motor neurones affords an explanation of the beneficial effects of massage, passive movements, and galvanism as stimulants to the regeneration of damaged nerve tissue. We also recognise the important influence that cheerful surroundings, sunlight, and other psychical stimulants may have upon morbid processes, and we admit the possibility that a powerful emotion may initiate a change for the better, either by stimulating the metabolism of diseased tissue or by opening up fresh paths for the transmission of motor or sensory impulses. As Dr. Mott points out: "Consciously and unconsciously, a continuous stream of impulses is pouring into the nervous system from without by the sensory channels, which are the avenues of experience and intelligence, and our bodily and psychical life depends upon the existence of such stimuli."

A consideration of these and of other facts which, as I have indicated, may be derived from a study of pathology and of the history of symptoms gives us hope for the future. It suggests that further investigations—clinical, pathological, and chemical—will do much to lighten the gloom which at present surrounds the prognosis of so many disorders of the nervous system.

**PLYMOUTH ROYAL EYE INFIRMARY.**—The formal opening of the Plymouth Royal Eye Infirmary took place on Oct. 30th, the ceremony being performed by Lady Mary Parker in the absence through illness of her mother, the Countess of Morley. There was a large gathering and the Earl of Morley made a strong appeal for subscriptions towards the deficit on the building, which amounts to £1300. £191 were subscribed at the meeting.

## An Address

ON

### THE PERSONAL FACTOR IN TUBERCULOSIS.

*Delivered before the Liverpool Medical Institution  
on Oct. 24th, 1901,*

By SIR DYCE DUCKWORTH, M.D., LL.D. EDIN.,  
F.R.C.P. LOND.,

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—It will not be denied that the art of medicine, and the science of pathology in particular, are at the present time largely dominated by conceptions derived from bacteriology. The progress of medical knowledge in the past has, with each fresh acquisition in any part of it, been commonly accompanied by a wave of enthusiasm which spread itself widely over the profession. In the face of any new revelations in science the tendency is to lose sight more or less of the older conceptions regarding the point in question. The lines of thought and action are henceforth projected vigorously in the new direction, and the older ideas, if not actually excluded, tend to be ignored or possibly forgotten. That this has occurred in respect of the doctrines of bacteriology can hardly be disputed, though all of us readily admit that these in themselves have constituted one of the most momentous triumphs of modern medicine. At such a time it becomes, as I believe, the duty of teachers of medicine to place these new doctrines in appropriate relation with those that have hitherto been held on the subject in question, and to indicate how the new teaching either supports or subverts the old. I have always agreed with the opinion expressed by the late Sir William Jenner that dogmatic teaching is essential for the student, and that it is unsafe, with a view to his future career, to allow many suggestions of doubt or any nebulous conceptions to occupy his mind. The faculty of apprehension and clear thinking has to be cultivated in the young. Doubts and difficulties will assuredly not fail to assail the mind in due time. Old or erroneous doctrines may then be more safely discarded and cut adrift, but they will be replaced by others; and the mature man, having learned to act on principles, will thus always have a faith to guide him. Otherwise he is apt throughout life to be the sport of shifting winds of doctrine and to be devoid of any firm or established principles.

I am led thus to preface the observations which I am about to make respecting the views which are at the present time much occupying the mind of the profession in regard to the modern doctrine of tuberculosis. We are apt to be enamoured by startling revelations in our art which disclose to us new vistas, and bid fair to herald the dawn of a day in which we are to be equipped with fresh powers wherewith to combat maladies which have hitherto baffled us. If we calmly take our course at such a time and are not so overcome by enthusiasm as to cast aside or to forget all the older conceptions that have been held on the particular subject we do well. I think that it must be admitted that some amongst us have been carried away by the latest teaching which has revealed to us the intimate nature of tuberculosis; that they have almost, if not altogether, lost sight of one of the most important elements concerned in the question—to wit, the *personal factor*, or the relation of the host towards the intruding and infecting parasite. Yet this is surely a matter of supreme importance. A perusal of most of the literature of the subject as presented to us to-day distinctly leads to the idea that human beings the world over are in constant risk of infection by tubercle bacilli, which are ever ready to alight upon them and to work out their malign developments in some fashion. I believe that there are not a few amongst us who are deliberately prepared to assert this view of the case. I propose in this communication to deny this conception, to try to indicate what manner of persons are those who most readily fall a prey to tuberculosis, and also to point out some of the conditions which prevail in those who manifest resistance to, or absolute immunity from, this scourge. We are familiar with the varying degrees of susceptibility to tuberculosis met with in different classes of

animals; in man there are evidently great differences in regard to predisposition to tuberculous infection, and the same varying degree of immunity is also witnessed in him towards many other infections.

In order to discuss this matter it is necessary to revert to some of the teachings of the older clinicians who had to face the problem in their day, and who, unprovided with the modern methods of research, formed opinions of weight and cogency, founded on close observation and a patient consideration of the facts which came before them exactly as they come before us. A study of their views should at once convince us that the whole field of clinical medicine is not covered by modern bacteriology, nor yet by modern pathology. As practising physicians we have to deal with humanity, that is, with individual human units, and the latter are not like so many ninepins turned off a lathe and out of one block. If we treat diseases and not patients, we may be scientists, but we are certainly not physicians.

It cannot be denied that the liability to tuberculous infection is limited, that certain persons are distinctly more prone to fall a prey to it than others, and that, happily, the majority of mankind presents a resistance to it, no doubt varying in degree, but in many cases amounting to practical immunity. It is surely important to recognise such facts, and to try to learn the significance of them if we can.

We have first to discover the peculiarities of those persons whose bodies afford a suitable nidus, or resting place, for the parasitic invasion and development of tubercle bacilli. This problem has only come before us since we have learned that a specific microbic and particulate element is the *causa vera* of tuberculosis. The older physicians had no such knowledge to guide them in their conceptions of the pathogeny of tuberculosis. The heredity of tuberculous disease was for them a fact which they could not dispute. Tuberculous parents produced children who sooner or later either developed the same malady or remained frail and delicate. This heritable tubercular tendency attached, as they believed, to the intimate textures of these individuals, and was ready, under certain provocation, to manifest itself in the lungs, skin, glands, or bones. Although they could find no morbid anatomy in such cases before the tuberculous process declared itself in some part of the body they regarded the quality, habit, and tendencies of these particular bodily tissues as differently endowed from those of robust persons void of this peculiar tendency. To this condition or diathetic habit of body they applied the term "scrofulous" or "strumous"—one seldom indeed met with in these days, and discarded for various reasons, none of which, I will add, appear to me to be justifiable. The word "scrofula" has always been offensive to the public and the term "struma" has often replaced it euphemistically. Both terms have almost ceased to have any significance in the professional mind since the discovery of Koch, and now we find it deliberately asserted by many pathologists that there is no such condition as that denoted by these words—that, in fact, struma is neither less nor more than tuberculosis. The recognition of Koch's bacillus has, in their opinion, compelled us to abolish the old conception of scrofula. No struma without tubercle bacilli, they affirm, and I suppose it will then be admitted that everyone infected with tubercle consequently becomes strumous. If this is the case, scrofula, as formerly understood, has necessarily ceased to be. As this idea has certainly been published and no one has ventured to offer objection to it so far as I am aware, I will strictly and absolutely deny this declaration. It is a narrow conception of the bodily condition denoted by the term "struma" to imagine that it is vulnerable alone to tuberculous influence, for it is oversensitive to all irritants and infections.

Let us inquire in detail as to the peculiarities of this condition of body as we recognise it clinically, for none but pure pathologists who are not practising physicians can possibly doubt its existence and wide prevalence. It is not in accord with modern teaching anywhere but in France to discuss or to appreciate any particular habits of body or diathetic conditions. These are now regarded as mediæval and effete lucubrations of the older physicians who evolved them out of their inner consciousness, as conditions which represent nothing that we, with our superior knowledge and attainments, can recognise nowadays. To hold such a view is, in my opinion, to be possessed of very inferior clinical instincts, and to be void of that accurate and penetrating observation which is necessary for the detection and comprehension of many morbid conditions which come before us.

According to Osler,<sup>1</sup> "scrofula is tubercle, as it has been shown that the bacillus of Koch is the essential element." As I have just remarked, many of our modern pathologists take this view. My friend Mr. W. K. Treves, of Margate, whose clinical experience is very large on this subject, and to whom I wrote for his opinion, believes that "scrofula is synonymous with tuberculosis in some form or other and that a scrofulous habit of body is already tuberculised." "Given no tubercular bacilli, there is no scrofula." He recognises, however, "a class of individuals who are especially liable to tuberculous disease in whom it is difficult to stop, and especially prone to recur." "They are flabby, inclined to stoutness, with a thick coarse skin, much cellular tissue, purplish or dusky complexion, and have a poor circulation," but he is not aware if such persons can be called scrofulous before they manifest tuberculous disease. He recognises, further, that these subjects are vulnerable to any variety of irritant and recover badly from injuries. "They are always catarrhal and suffer from congested and unhealthy throats." I am in full agreement with the latter observations. They relate to the class I have in my mind, to those who are as yet free from tuberculous manifestations, although especially prone to be infected. They are of a scrofulous or strumous habit of body, as yet untainted. We surely see many examples and we certainly cannot regard them physiognomically or texturally as types of any other condition than that of scrofula. To use Sir John Simon's<sup>2</sup> words, I would regard such subjects as "inheritors of an imperfect pattern of development" in the same way as we conceive others to inherit a disposition to gout, rheumatism, or cancer, "an inherited personal and particular law of development, which affixes a something peculiar and individual to their passage through each period of their existence."

Sir Thomas Watson<sup>3</sup> held the same opinions. "The formation of tubercle," he wrote, "is closely linked with the existence of the scrofulous diathesis," but he distinctly recognised scrofulous manifestations as occurring independently of tuberculation, and noted that the latter was modified by the variety of inflammation which existed in the scrofulous subject, a point that has received but little recognition anywhere. I will grant that the term "scrofulous" is inadequate to express all that is properly denoted by it. Originally, it was applied to the swollen condition of the neck due to adenitis and periadenitis, whereby the patient thus affected assumed somewhat the aspect of a breeding sow (*scrofa*), that is, void of the ordinary constriction of a human neck, and the term "struma" was also employed to denote a scrofulous swelling. But this condition, as rightly understood, is not expressed merely by a local adenitis, which is but one indication of it. A scrofulous habit of body means a great deal more than this. It may be etymologically correct to regard a cervical adenitis as scrofula, but from a clinical point of view we must have regard to a widely-spread and specific quality of tissues which is impressed upon the entire organism. No more classical description of the physiognomical features of this habit of body has ever been given than that by Watson. It was founded on shrewd observation, and the portraiture thus depicted is not seldom brought before us, and may be recognised if we will but honestly regard it. The two types of "pretty" and "ugly" struma are still with us, and we can plainly see that they are the products of the same disposition, though modified. With our present knowledge of the influence of hereditary syphilis on the bodily textures we have no need to regard the features of the "ugly" variety of scrofula as modified by that particular taint. It would be well if the younger physicians read and pondered Watson's lucid lectures on the scrofulous habit of body. Modern text-books completely ignore this teaching and appear to regard the whole question of tuberculosis as finally settled by Koch's discovery. This is certainly not the case. Albeit, we are not to expect to recognise the features of scrofula in their classical form in every example of it, but we may often discover the presence and influence of this constitutional frailty by a study of the ailments, and the special characters they assume, in those who are impressed by it.

The opinion of Sir James Paget on this matter was clear and decided. He defined "scrofula, or struma, as a

<sup>3</sup> Lectures on the Principles and Practice of Physic, fourth edition 1857, vol. i., pp. 195, 204; and vol. ii., p. 206.

state of constitution distinguished, in some measure, by peculiarities of appearance even during health, but much more by peculiar liability to certain diseases including pulmonary phthisis. The chief of these 'scrofulous' diseases are various swellings of lymphatic glands, arising from causes which would be inadequate to produce them in ordinary healthy persons. The swellings are due sometimes to mere enlargements, as from an increase of natural structure, sometimes to chronic inflammation, sometimes to more acute inflammation or abscess, sometimes to tuberculous disease of the glands. But besides these, it is usual to reckon as 'scrofulous' affections certain chronic inflammations of joints, slowly progressive ulceration of bones, chronic and frequent ulcers of the cornea, ophthalmia with extreme intolerance of light, but with little of the ordinary consequence of inflammation, frequent chronic abscesses, pustular cutaneous eruptions frequently appearing upon slight affection of the health, or local irritation, habitual swelling and catarrh of the mucous membrane of the nose, and habitual swellings of the upper lip. .... Certainly these are not all tuberculous diseases." <sup>4</sup> The term "scrofula" includes, he declared, some diseases which are, and many which are not, distinguished by the production of tuberculous matter. Alluding to the proposal to make "scrofulous" and "tuberculous" commensurate terms, he considered it to be doubtfully practicable. "The relation between the two is that the scrofulous constitution implies a peculiar liability to the tuberculous diseases, and that they often coexist." "Many instances of scrofula exist with intense and long-continued disease, but without tubercular deposit, and as many instances of tubercular disease may be found without any of the non-tuberculous affections of scrofula."

These opinions were published long before the discovery of tubercle bacilli, and it has still to be shown that all the alleged scrofulous disorders just described are aroused by, and dependent upon, tuberculous invasion or its influence in any form. I greatly doubt if this can be proved. No one would venture to assert, for example, that ciliary blepharitis, so common in strumous children, is dependent on tuberculosis. We must then regard it strictly as a variety of strumous inflammation. Paget was cautious in stating that the substance found in lymphatic glands commonly known as "scrofulous" matter could not for certain be known as truly tuberculous matter or degenerate lymph or pus. We can tell now whether this be so or not, and may discover that sometimes we are dealing with the one and sometimes with the other.

In discussing this question, Professor Clifford Allbutt <sup>5</sup> remarks: "Whether scrofula is always due to the tubercle bacillus, or always associated with it, is not yet decided. It seems probable that scrofula may arise by the agency of microbes other than tubercles; again, that, originating independently of tubercle, on it tubercle may afterwards supervene; and, once more, that scrofula may be due to tubercle, primarily or even exclusively. No doubt these problems will soon be settled." These hypotheses indicate a shaking of the old faith which has occurred since Koch's discovery. I do not believe that we have sufficient justification for a change of opinion on this matter. We see more clearly how certain conditions, induced either by inheritance or by acquirement, provide a suitable soil for the specific infection. <sup>6</sup> Respecting acquired conditions which may render persons of originally good constitution liable to tuberculous infection, we know that these are all of a character to induce a lowered vitality and so to render the bodily textures unfit to resist the onset of tuberculosis. The inherent immunity appears to cease with a lowered standard of health, more or less according to the nature of the debility and the degree of intensity of the infection. I hold, then, that a scrofulous person is not, and need not be, a tuberculised person.

We meet with another class of subjects who present a marked resistance to tuberculous invasion in those who manifest a proclivity to gout. In the offspring of gouty parentage and

ancestry it is most rare to meet with any strumous indications or disorders. Tuberculosis in a gouty subject is rarely witnessed and, in my experience, its progress is either very slow or apt to be arrested. There is thus a manifest antagonism between a gouty and a strumous proclivity. We may further note that a line of treatment which is appropriate to those who are goutily disposed is unsuitable for strumous subjects, and that what is bad for the gouty is good for the scrofulous—to wit, animal food and wine. The presence of a strain of gout in a strumous subject is thus a saving grace for the individual, modifying the tendency and course of any manifestation of the latter in a favourable way.

I maintain, then, that there is a class of persons who by inheritance, or acquirement, owing to various debilitating conditions, are frail and delicate, endowed with a specific proclivity to become gravely affected by irritants of all kinds, and especially prone to infection by tubercle bacilli. Such persons are of delicate constitution and are apt to manifest this delicacy in various ways throughout life, such developments indicating their scrofulous habit of body. They may never become tuberculous, although always scrofulous. The latter proclivity may blend with other habits of body and seriously modify the ailments induced by them. We have not to wait for tuberculous invasion to occur before we pronounce them scrofulous, since they carry with them the features and characteristics of the scrofulous condition beforehand.

It is therefore a question of tissue or soil-proclivity in the particular host which is to harbour the tuberculous microbe. The ailments of the strumous individual are not necessarily of a tuberculous quality, and the error in modern teaching, as I believe, is to assert that this is the case. When tuberculosis occurs at any point in a strumous subject we must certainly regard it as such, but we have no justification in assuming the existence of it before such manifestations are present. Some have imagined that the indications of scrofula, as properly recognised, are due to the existence of some pre-existing condition of tubercle bacilli in the tissues, but we have no knowledge of such a condition, nor, indeed, of the extra-corporeal stages or environments of the bacillus anywhere. It has even been asserted that the hereditary transmission of the microphyte constitutes the unique and exclusive method employed by nature to propagate tuberculosis, but these organisms are then in a purely passive or latent condition. If no active tuberculosis occurs during the life of the affected individual the germs are supposed never to have been aroused into activity. <sup>7</sup> This is, of course, a pure hypothesis and cannot be accepted without absolute proof (Cohnheim and Baumgarten). We have some trustworthy facts to support the belief that the foetus in utero may be directly infected by tubercle bacilli. Women suffering from advanced phthisis have borne children in whose organs—lympharia, liver, spleen, lungs, and endocardium—have been found bacilli of tubercle. The placenta is infected in these cases and is doubtless the medium of contamination. Dr. J. W. Ballantyne of Edinburgh, who has reported cases of this kind, believes that the problem of tuberculous heredity pertains to the germinal period of intra-uterine life, <sup>8</sup> and wisely remarks that "a healthy placenta is the best friend that the foetus of a tuberculous mother can have." <sup>9</sup> With these facts before us we cannot deny the direct transmission of tuberculosis as a possibility, but there is no reason to believe that such instances are of common occurrence, and we can in no way admit that they alone constitute the type of case which should be regarded as scrofulous, for these infected subjects are either still-born or, if born alive, not viable. A similar transmission is met with, though rarely, in the calf.

I have already quoted the opinion of Osler to the effect that "scrofula is tubercle," but I find that he materially qualifies it, if he does not practically deny it, by adding, "After all, as Virchow pointed out, increased vulnerability of the tissues, however brought about, is the important factor in scrofula." That is exactly my contention.

There remain to be mentioned, amongst causes which diminish resistance to tuberculous invasion, or in other words, promote proclivity or vulnerability to it, the abuse of alcohol, the occurrence of syphilis, of saccharine diabetes,

<sup>5</sup> System of Medicine, 1897, vol. iv., p. 597.

<sup>6</sup> Professor Martius of Rostock (German Association for the Advancement of Science and Medicine, Hamburg, September, 1901) recently expressed the opinion that heredity, as regards tuberculosis, did not necessarily mean that the tubercle bacillus was present in the spermatozoon or the ovum; it meant the transmission of predisposition to tuberculosis, and there was abundant evidence to show that predisposition existed. On this point Dr. Percy Kidd's article on "Phthisis Pulmonalis" in Allbutt's System of Medicine (vol. v., p. 171) may be consulted.

<sup>9</sup> Lecture at the Polyclinic, London, 1899.

and of cancer, the latter proving inimical to the spread of it, as Dr. Sidney Martin has pointed out, even if the condition induced by it tends to invasion of the body.

I have alluded to the specific changes accompanying tuberculosis which are witnessed in scrofulous subjects. The process is modified in them, and the associated inflammatory products tend to soften and break down. In the case of gouty subjects the process is varied; there is less tendency to soften, and the products tend towards sclerosis, fibrosis, and calcification, thus inducing arrest and obsolescence of the lesions. We thus see how the particular habit of body avails to modify the phenomena and course of a definite infecting process. I maintain that these facts in pathology are now too much lost sight of, and that we have been of late too much concerned with the bald facts of bacteriology and infection in regard to the whole subject of tuberculosis. We must turn aside and consider the condition of the host in this matter.

We may, I believe, regard it as certain that for the production of tuberculosis two factors are necessarily concerned: (a) the parasite, and (b) the nature and condition of health, or diathetic habit, of the host. Our modern pathologists "reckon without their host." We fail in comprehending many pathogenic conditions if we disregard the personal factor in each case. Thus, uricæmia as one factor does not explain the production of gout; rheumatic poison as a single factor will not explain the production of chorea. In these and other morbid states, the condition of the organism, attacked or invaded by matters which are toxic to it, has to be reckoned with, and its determining influence for good or for evil is of supreme importance. If we pay due heed to this question, we cannot fail to see that our duties lie in the direction of fortifying by all means those subjects who from any cause are more than others prone to infection. Our warfare is not to be confined to the parasite alone. We do well to intercept it and to destroy it everywhere. But we have also to make our frail and predisposed subjects robust by securing for them appropriate environment and adequate and suitable dietary, and to follow up their special ailments with assiduity till recovery is well established. We come too late into action if we wait till the enemy has entered the gates. We have to anticipate his assault and to challenge his entry. If we do this, and thus pay due regard to the personal factor in tuberculosis, which, from a clinical standpoint, as I maintain, we are bound to do, we shall not improbably do more to avert this terrible scourge from humanity than by any other course of procedure we may decide to follow.

Lastly, I will venture to say that we hear too much in these days of the so-called "cure" of tuberculosis. This is an improper term to apply to cases of this disease which have progressed favourably and in which the local disorder has become quiescent. As we well know, there may not seldom be a recrudescence and a relapse of the process at any period during the lifetime of the patient. We are not entitled to regard the most favourable termination of tuberculous lesions as constituting anything more than an arrest of the process, as has been well pointed out to us by Dr. James Edward Pollock, Dr. C. Theodore Williams, and, more recently again, with all the weight of his authority, by Virchow. If we can determine the peculiar habit of body and predisposition of the affected individual, we may sometimes be enabled to frame a more certain prognosis as to the quality and completeness of the arrest in particular cases. More than this we cannot do.

## THE FREEZING-POINT OF THE BLOOD AND SECRETIONS AS AN AID TO PROGNOSIS.

By ALEXANDER OGSTON, M.D. ABERD.,

REGIUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF ABERDEEN;  
CONSULTING SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

THE use of the thermometer in medicine and surgery has already been of much value in the study of disease, and though in some respects, such as surface thermometry, it has not gained for itself a recognised position, yet the appreciation of the information obtainable by the use of the clinical thermometer has become steadily greater as our experience and knowledge of it have extended.

Another employment of thermometry, in quite a different

direction, has recently been introduced on the continent, and is destined, I think, to attain a very high place in the estimation of the clinician, whether medical or surgical, on account of the valuable data which it is able to afford us regarding certain questions, otherwise scarcely to be solved, which call for an answer when grave decisions regarding prognosis and treatment are to be reached. I refer to the use of cryoscopy, or the determination of the freezing-point of fluids.

Van't Hoff and Raoult pointed out that fluids freeze at a lower temperature in proportion to the quantities they contain of impurities dissolved in them; and Korányi, applying the law to the blood and urine, showed that normal blood possessed a fixed freezing-point of  $0.56^{\circ}$  C. below that of distilled water which forms the zero of that thermometrical scale. From this point it does not vary more than by one-hundredth of a degree up or down. Urine is not so steadfast, varying in its freezing-point about a whole degree, from  $-1^{\circ}$  to  $-2^{\circ}$  C., in proportion to the solids which it contains in a state of solution.

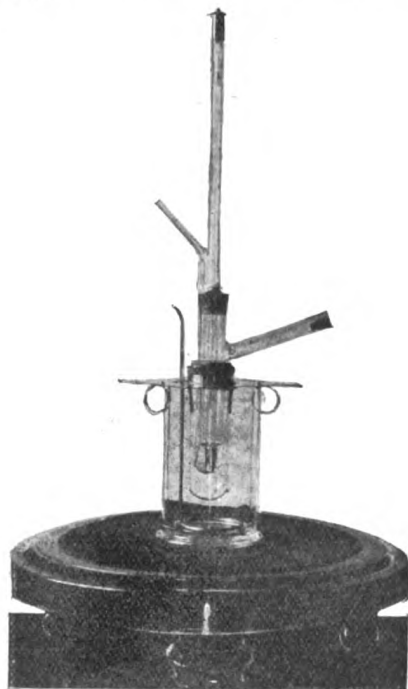

Korányi's observations have been applied to the study of abnormal blood by many German and French writers—Lindemann, Dreser, Richter, Roth, Senator, Claude, Balthazard, and Kümmell, particularly by Kümmell, an eminent Hamburg surgeon. Their conclusions may be thus briefly stated. So long as the blood is healthy and has its effete constituents adequately eliminated it retains, as already said, its normal freezing-point—viz.,  $-0.56^{\circ}$ , or within  $\frac{1}{100}^{\circ}$  of that figure, varying, that is to say, from  $-0.55^{\circ}$  to  $-0.57^{\circ}$ , but if elimination becomes defective the freezing-point sinks below this—to  $-0.58^{\circ}$ ,  $-0.60^{\circ}$ , even to  $-0.71^{\circ}$  in one case observed by Kümmell.

The attention of these observers appears to have been mainly directed to the purification of the blood effected by the kidneys, regarding the measurement of which our present knowledge is admittedly defective and where consequently the value of cryoscopy promises to be great.

That our present information regarding kidney elimination is inadequate is constantly felt by surgeons where renal disease is present in a patient requiring operation. We strive in such a case to ascertain how much disease exists; whether the amount of healthy kidney substance be still sufficient so to purify the blood that our operation wounds will heal well; further, whether the lessened kidney elimination that follows operations, especially if performed under an anæsthetic, superadded to the already existing defect, is likely to kill our patient; and, lastly, where the kidney itself is to be operated on, whether the other kidney be sound enough to take over the eliminative work of the two organs. To all these questions, hitherto imperfectly answerable, the use of cryoscopy promises to furnish a definite and satisfactory reply. I believe, too, that it will prove to be of no less value in determining the existence and degree of hepaticism, when threatening danger to life or imperilling operations, a condition regarding which little that is satisfactory has hitherto been written although its importance is acknowledged by every surgeon of experience.

The determination of the freezing-point is carried out by Beckmann's apparatus (see illustration), consisting of a jar of ice and salt into which dips a large test-tube, into the mouth of which is inserted through a perforated cork a smaller test-tube about an inch in diameter, so that an air-chamber is left between the tubes. The fluid to be frozen is put into the inner tube. The thermometer used is Beckmann's thermometer, the scale of which has a range of only  $6^{\circ}$  C., each degree being divided into hundredths, the numbers running from  $0.00^{\circ}$  to  $6.00^{\circ}$ . On this scale the zero, that is, the freezing-point of distilled water, has first to be found, distilled water being for this purpose placed in the inner tube and the thermometer plunged into it until its bulb is covered. The freezing mixture cools the fluid and the mercury first falls down to, and then descends a couple of degrees or so below, the freezing-point. At the moment at which congelation begins the mercury rises again quickly and within a few minutes attains a steady maximum, which is the true freezing-point. During this observation the fluid is kept constantly stirred by a ring-shaped platinum stirrer that passes down between the inner tube and the thermometer. If the zero thus found be above the six degrees given on the scale a little mercury is shaken off the column into a reservoir which exists for the purpose at the upper end of the thermometer; or if, on the other hand, it be below the scale, some mercury is shaken

from the reservoir into the column until the zero falls somewhere in the upper end of the scale. This point is then noted, and all calculations of temperatures below zero are found by subtracting from it. If, for instance, the zero were  $4.01^{\circ}$ , then the normal freezing-point of blood is  $3.45^{\circ}$ , that is  $0.56^{\circ}$  lower.

Beckmann's freezing-point apparatus.

In cryoscopy of the blood the sample to be tested may be drawn from any large vein about the hand, wrist, or forearm, or in the usual venesection position at the bend of the elbow. It may be drawn directly into the apparatus or, better, into a stoppered bottle where it can be secured until the cryoscopy is conveniently applicable. Coagulation makes no difference to its freezing-point, which is found in the manner just described for obtaining that of distilled water. When once the zero of the thermometer has been accurately determined it is necessary that it be carried very gently and subjected to no jarring or agitation, lest its correctness be impaired by shaking mercury into or out of the column. As the instrument is made of Abbé's glass, the zero remains without alteration from subsequent contraction.

Other fluids of the body besides the blood may be tested by cryoscopy. Kümmell applies the process to the urine from both kidneys as it is passed from the bladder, or to that drawn off from a single ureter, and combines it with the administration of phloridzin, &c., thus testing the eliminating power of the organ. Personally I have also so employed it, but have ceased to use it, as the freezing-point fluctuates more than an entire degree, thus giving no better indication of the quantities eliminated than may be obtained in much less time by taking the specific gravity. I have also used the method, or endeavoured to do so, in testing the saliva from Steno's duct, but it is difficult to apply and has no special advantage. But in regard to the blood it would be difficult, I think, to exaggerate the usefulness of cryoscopy, or the accuracy of the information which it places at our disposal. Brief notes of some of the cases where I have found it useful may render this evident.

CASE 1.—The patient had for three years been recovering from an attack of double interstitial nephritis, and traces of albumin were still always present. The specific gravity of the urine was 1020 and he was so strong and well that he desired to resume his studies for the Church. His blood froze at  $-0.53^{\circ}$ —i.e.,  $1\frac{3}{8}^{\circ}$  higher than normal. He resumed his studies.

CASE 2.—A patient under the care of Dr. J. Stephen of Peterhead wished to undergo a radical cure of an inguinal hernia. His urine was free from albumin or sugar and he

appeared to be a very strong man; but a slight yellowness of the conjunctiva suggested hepatism, that insidious foe of the operating surgeon. His blood froze at  $-0.58^{\circ}$ —i.e.,  $1\frac{3}{8}^{\circ}$  below normal. The operation was declined and a truss was fitted. He died four months later. This patient would certainly, save for the cryoscopy, have been operated upon, and probably with a fatal result.

CASE 3.—A patient who was under the care of Professor W. Stephenson wished to undergo an operation for relapse of a ventral hernia after a previously attempted radical cure. Her blood froze at  $-0.72^{\circ}$ —i.e.,  $1\frac{3}{8}^{\circ}$  below normal, her urine at  $-1.775^{\circ}$ . In this case the usual routine urine examination detected glycosuria and the cryoscopy merely confirmed the existence of the disease. Operation was declined and a truss was used.

CASE 4.—A patient under the care of Dr. T. B. Gibson with symptoms of unilateral renal disease, probably calculous, where radiography had failed to reveal anything, in whom the analysis of the catarrhal urine showed a specific gravity varying between 1004 and 1018, but whose general condition made the prudence of an exploratory nephrotomy questionable, had cryoscopy applied to the blood. It froze at  $-0.54^{\circ}$ —i.e.,  $1\frac{3}{8}^{\circ}$  above normal. Operation was therefore decided on so soon as the patient's circumstances permitted. Here it is to be noted that while the cryoscopy of the blood furnished a satisfactory verdict that of the urine was as indefinite as its specific gravity, for it varied between  $-0.46^{\circ}$  and  $-1.49^{\circ}$  in the same day.

CASE 5.—The patient was under the care of Dr. J. D. Wyness. He suffered from bladder paralysis due to many years' neglect of a cicatricial stricture that admitted only minute bougies. The stricture was dilated and the bladder paralysis was treated by Dr. J. R. Levack with faradisation without removing the paralysis. The patient lived a catheter life, but without any trouble. His urine had a specific gravity of 1010, contained no sugar or albumin, and the question arising whether he should resume his ordinary life and work it was answered in the affirmative by the freezing-point of his blood, which was  $-0.56^{\circ}$ .

CASE 6.—The patient who was under the care of Dr. R. S. Turner of Keith, had a cystic fibro-sarcoma of the left kidney as big as a child's head. She was 71 years of age, and the propriety of operation had to be determined. Her urine had a specific gravity of 1016 to 1015, was free from sugar, but sometimes contained traces of albumin, sometimes none. The freezing-point of her blood was  $-0.556^{\circ}$ , faintly above normal, and hæmacytometry showed the red blood corpuscles numbering 4,560,000 instead of 5,000,000 per cubic millimetre, while the leucocytes were four times more numerous than they ought to have been. The cryoscopy of the blood did not alone, perhaps, decide in this case whether the operation for removal of the tumour was or was not justifiable, but it was slightly unfavourable and enabled a truer view of the patient's condition to be obtained than was otherwise practicable. The decision was against operating, at least in the meantime.

CASE 7.—A patient under the care of Dr. J. Pender Smith of Dingwall who was operated upon for cæcal cancer lost strength steadily after the operation. The urine had a specific gravity of 1021; it contained no sugar, but was albuminous. Here the blood cryoscopy, which showed a freezing-point of  $-0.49^{\circ}$ , or  $1\frac{7}{8}^{\circ}$  above normal, showed that the kidneys, though diseased, were not the cause of the deterioration.

CASE 8.—A patient under the care of Dr. Ashley W. Mackintosh suffered from retention of urine due to an old urethral organic stricture admitting a catheter of No. 6 English scale. The urine had a specific gravity of 1006 and was albuminous. His blood froze at  $-0.59^{\circ}$ , or  $1\frac{3}{8}^{\circ}$  below normal, showing that the kidney elimination was imperfect, and that, though apparently a strong and healthy man, he was approaching uræmia, and was an unfit subject for treatment by operative measures.

CASE 9.—The following case bears on the subject of hepatism. The patient, who was under the care of Dr. Gibson, had an *évident* of a suppurating bursa of the great toe carried out under chloroform. The anæsthetic produced great general disturbance, jaundice, vomiting, and stomach disorder. The urine, which was of specific gravity 1026, was albuminous, but there was no sugar, while the blood froze at  $-0.62^{\circ}$ , or  $1\frac{3}{8}^{\circ}$  below normal, a result due to the liver disturbance more than to that of the kidneys.

CASE 10.—The patient, who was under the care of Dr. A. Mitchell of Old Aberdeen and of Professor J. T. Cash, was

suffering from an old empyema. She was greatly wasted by suppuration and amyloid disease, with albuminuria, 238 grains of urea being eliminated per diem by the kidneys. She had clubbed fingers, and she appeared to be in an evil case. But the cryoscopy of the blood showed  $-0.57^{\circ}$ , or only  $1\frac{1}{2}^{\circ}$  below normal, and an extensive operation was successfully ventured upon on the faith of that observation.

CASE 11.—A patient under the care of Dr. W. Hector of Tarland had prestatic hypertrophy and violent cystitis as the result of many years of disease. Irrigation and catheterism answered for a time, but hæmaturia of an obstinate nature set in. Double vasectomy cured the hæmorrhage and greatly diminished the enormous prostate. But the pain and cystitis recurred, and the patient's sufferings became so violent that bladder drainage through the perineum was inevitable, whatever the consequences might be. Albuminuria, with urine of a specific gravity of 1010, left the renal condition uncertain; but cryoscopy of the blood showed  $-0.61^{\circ}$ , or  $1\frac{1}{2}^{\circ}$  below normal. Still the operation was absolutely necessary to relieve the pain, which narcotics and all other measures entirely failed to do. It was followed in a few days by uræmia and death.

CASE 12.—The patient, who was under the care of Dr. C. Adam of Elgin, had suffered from phlegmasia dolens for some years and had recovered, but lately the swelling had recommenced. No phlebitis or lymphadenitis was found, but a mere trace of albumin and a low specific gravity (1002) of the urine threw suspicion on the kidneys. This was confirmed by cryoscopy of the blood, which showed its freezing-point to be lowered to  $-0.59^{\circ}$ , a condition due, almost certainly, to defective elimination by both kidneys.

These 12 cases, to which I might add more, illustrate the services which cryoscopy of the blood is in a position to render under circumstances in which we have hitherto had little more than conjecture to aid us and they justify the expectation that the method will soon be universally adopted. In Cases 1, 4, 6, and 7 it will be noted that the blood froze from  $1\frac{1}{2}^{\circ}$  to  $1\frac{1}{2}^{\circ}$  above its normal point. Cases 6 and 7 were hydremic, but Cases 1 and 4 showed no signs of either that or anæmia. Possibly a condition of unusual purity of the blood may exist, with a higher freezing-point than normal, but what is the significance of such an elevation of its freezing-point in these cases I am unable to say. It will, I suspect, prove to be a symptom of disease. In Cases 2 and 9 the lowering of the freezing-point was clearly owing to hepatic, not renal disease, and I am of opinion that not the least valuable import of cryoscopy will be its power of indicating otherwise undetectable disease of the liver, at least in the practice of the operating surgeon.

## THE SANATORIUM IN THE TREATMENT OF PHTHISIS.<sup>1</sup>

By T. CLIFFORD ALLBUTT, M.D., LL.D., D.Sc., F.R.S.,  
F.R.C.P. LOND. AND IREL.,

REGIUS PROFESSOR OF PHYSIC, UNIVERSITY OF CAMBRIDGE;  
PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

My interest in this subject was first aroused by Dr. Archibald Smith, of Lima, with whom I had some acquaintance in the "eighteen-sixties." He spoke, for the first time in my experience, with confidence of the curability of the disease, especially as treated in the mountains of Peru. These new hopes were fortified by Henry Bennet, with whose methods and results I became familiar, both in his writings and in personal association with him at home and in the Riviera. The first records, of any considerable

value, of the effects of various methods of treatment of the disease were published by Dr. C. J. Williams and Dr. Theodore Williams in 1871, records which did much to instruct and to encourage us. Bennet's influence drew me away for a time from the High Alps as a climate for phthisis, but in 1878 I, after occasional observation of a few cases treated in the Swiss Alps, made the acquaintance at Davos of Dr. Unger and Dr. Ruedi, and I then formed great anticipations of the value of Alpine climate—anticipations which 25 subsequent years have strengthened and formulated.

At that time climate seemed to us to be the paramount factor in the cure; so our admiration was the greater as the remarkable results obtained by Brehmer at Görbersdorf rose into repute, results in which climate played but a secondary part. Brehmer's method, to which nothing important has been added by later physicians, brought the cure of phthisis from a remote and costly achievement, attainable only by wealthy and leisurely patients, near the doors, I had almost said into the homes, of poorer sufferers given up to death. We did not realise the facts which the computations of Birch-Hirschfeld and others have placed beyond question, that then, as now, many persons were recovering from pulmonary phthisis under our eyes; our eyes were not open to see it.

By the modern method we are not only curing the individual, but we are also laying the chief stone of the edifice of prevention. This modern method we may call the method of Brehmer; but it is called more commonly the sanatorium method. To this name some objection has been made; it is said that the method may be carried out independently of the sanatorium. We cannot be guided by the etymology of names—no name can indicate all the connotations of its subject; but I think that this objection is a shallow one. The method was worked out in a sanatorium created for the purpose, it has been tested and perfected in sanatoriums, and if now it can be carried on outside a sanatorium, which is not too readily to be admitted, this is so only by bringing the skill and the conditions of the sanatorium into the home. I should look with little confidence on the home treatment of a phthisical patient by a physician unversed in the practice of the sanatorium, and by a patient who had not had at least a month's training within its precincts. It is, as it were, to tell a boy at home to read his Cæsar and his Xenophon, a little Euclid and algebra, to pat him on the head, bid him be good and industrious, and promise to call in a week or ten days to see how he has got on.

It is no paradox to say that in the congregations of the sanatorium we have learnt individual treatment; that from institutions which may well sink into the thralldom of routine, or lend themselves to the grosser temptations of the hotel-keeper, has issued the doctrine that for the individual sufferer no vigilance is fastidious, no skilled control vexatious. From a highly specialised system we have learnt that for phthisis there is no specific—not even climate; that to speak of the best climate for phthisis, of the best mode of feeding, or again of the best disposal of rest and exercise, is to speak vainly. For scrofulous children, as a rule, the best climate is the sea; for the adult in the third or fourth decade of life the climate of the high Alps, less windy than the sea, even more tonic and perhaps having some virtue in its dryness and rarity, is often the best; the elderly must be content with a milder and more equable resort, which indeed is to be preferred also for many younger patients whose stomachs are unequal to large demands, and whose heat production is slow. On the robust folk full feeding may be pressed quickly; with the enfeebled, whose stomachs are often relaxed, large and rich meals best agree when they are vomited. To the febrile and overwrought again that prolonged rest, which in vigorous and apyretic persons would be lost time, is precious.

The sanatorium, if on the block system, should stand south-east, on a dry upland site sheltered by pine woods, 200 yards at least away from the building. The front should be slightly crescentic. Most of the rooms should be single, a few may be double for special needs. All must be on the front, the back being given to the service, and to the accommodation of an occasional visitor. The smaller the bedroom, within limits, the better, lest it be used as a sitting-room, whereas it is but a shelter for the bed and for dressing and undressing. There should be no general sitting-rooms, which encourage indoor gossip, except, of course, a dining-room and a spacious and airy entrance-hall on the south front. Every room should have its covered

<sup>1</sup> A paper read before the British Congress on Tuberculosis, Section II., Medical, including Climatology and the Sanatorium.

balcony, wide enough to take the long chair (or bed) and a table, separated by glazed screens from those next to it, and supplied with convenient electric light. The balcony is the living room of the patient. Airing galleries may be provided for the few who may like them, but they have social and other disadvantages. The balcony, if raised a step or two above the bedroom floor, will not shut out much light from the window below, at any rate not in winter, when the sun is low. Of walls and furniture I will only say that the doors should be double and the walls and floors without angles and well pugged; that wardrobes should be built in the walls, flush with them and the ceiling; that linoleum, with felt under it, makes the most comfortable and the cleanest carpet. The window must occupy the greater part of the south wall, and sliding shutters with louvres must be provided to darken the room for light sleepers, and against stormy weather. Heating is a great difficulty. Open fires, if practicable, are by far the best means of heating. If impracticable the walls should be heated by flues. To heat the air to be respired is wrong, both in principle and in practice. If so-called "radiators" must be used, the radiator must be set against an opening in the outer wall, and the air led over it into the room so as to enter the room at the bottom. Hot air rises, and, do as we may, the inmate of a room so heated is hot in the head and cold in the legs and feet. The roof must be warm in winter and cool in summer. If all passages and corridors be well and equally warmed the heating of the chambers will need less attention.

It is undesirable that patients should take their principal meals in the private room and a dining-hall must be provided; but I have received a bad impression of the dining-rooms of most of the sanatoriums which I have visited. Either they are a whirlpool of draughts, wherein the poor patients can scarcely keep their hair on, or they reek with foul odours. The director of a sanatorium, in many ways admirable, lately ushered me with pride into a handsome dining-hall whose close atmosphere was so thick with the reek of departed dinners that I sickened on the threshold and, muttering some excuse, made my escape. Most of these halls are much too high and not thoroughly air-swept; others are ordinary apartments with the windows taken out, so that the patient must dine in a hurricane, bolting his food and surrendering whatsoever charm dinner might yet have for him. Saloons should give place to sheds or bungalows with sliding walls of louvred shutters which can be adapted to the wind of the day, and afterwards quickly thrown open for coffee and cigarettes, when each patient can sit where he pleases.

If, in obedience to the needs of municipal or other public bodies, such sanatoriums must be built to receive more than 50 patients a physician must be engaged for every multiple of 50—the largest number of patients to which any man can do well. Let us not tolerate again the farce of so-called medical attendance which still persists in many asylums for the insane, to the grievous loss of science and to the detriment of the sick. But in my opinion sanatoriums are designed so large and costly as to deter the benevolent and to encumber the treatment. A hut or villa system in the grounds about a central administrative block is cheaper, more homely, and more efficient. The Japanese house is a good model. The difficulty of ventilating large blocks is insuperable; they will beget the secretary-director, and lead to a barrack or hotel system. Tents are useful, but for temporary purposes only. Ordinary dwelling-houses converted into sanatoriums are makeshifts at best, and unsatisfactory at that.

I repeat that it is vain to talk of a "best climate" for phthisis, even for those who can go where they please. Sun is an amenity and a cordial, but does not directly contribute much to the cure. At Davos the patients do as well in the darker as in brighter winters. Gabrilowitch, at Halila, compared the reports for the winter six months with those of the summer six months, and found that the winter patients did considerably better than the summer patients, the bracing air of winter, in spite of less light, being more restorative. For the most general terms in which climatic conditions can be put is that the coldest air which the individual can tolerate, if it be dry, clear, and still, is the best, as it calls for more food and thus stimulates the appetite. But in an air so cold as to be very stimulating to a patient of 35 years of age, a patient of 55 years of age would shrivel up. Thus it is for the younger patients of fair vigour that the high Alpine airs are the best; say for vigorous persons under 40 or 45 years of age without much bronchial irritation. At Davos it is wonderful to

see a wan listless youth for the first few days picking daintily at his half-eaten meals, and 10 days later devouring all before him. At lower altitudes some urgent feeding may be needed, but in any fresh open air a naturally good feeder soon regains appetite; and to force him before nature calls is too often to lose a week or two in an attack of indigestion. In England, Norfolk, Suffolk, and Kent offer the best climates for the phthisical. A poor eater does badly in any climate and under any stuffing. Appetite again much depends upon the preparation of the food, especially among the wealthier classes. The meals, even in the more luxurious sanatoriums, are too often badly cooked and badly served, good as the raw materials usually are. The dishes and plates are cold, the meats are tepid, and the coffee and tea are scarcely fit to drink. All bread, rolls, and cakes should be baked in the house. A variety of dishes, again, as city diners know, tempts to repletion; yet sanatorium cooks do not stand alone in their contentment with a narrow round of menus, which, attractive enough at first, begin, perhaps after a week or two, to pall upon the palate. The physician of a sanatorium should be something of a cook and much of a gourmet.

For the encouragement of scientific work in sanatoriums, which in the nature of the case are far from the advantages of large towns, there should be central committees. Such a committee in England—let us say a branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis—would organise the methods of reporting, would suggest the kind of information needed, would circulate scientific results among these institutions, and would point out the many directions in which investigation is needed. Excellent work of this kind is now done in a few sanatoriums, but there is a fear lest the medical officers should fall into the supine routine of too many of the asylums for the insane. Or, again, work may be active but ill-directed. Every sanatorium deservng the name has its laboratory; but how much valuable time is wasted in the counting of bacilli! Such computations are necessary from time to time, no doubt; but daily or even weekly fluctuations are too dependent on temporary contingencies to be worth much, and there are more important things to be done. For instance, I may suggest examinations of the blood, the comparison of its cells, and of the fluctuations of its specific gravity; the study of its sera for agglutination, toxins and antidotes, and their relation to the tuberculin; the attenuations of virus by inoculation and other methods; the estimation of the virulence rather than of the number of bacilli in the sputa; the evidences of mixed infections such as cocci in the blood; the investigation of the possible harm of re-infection by tubercle, as, for example, by soiled fingers, tooth-brush, or swallowed sputum; the secretions of the stomach at various phases of digestion; examinations of the urine for toxins, for the comparison of ingestion and excretion, for the influence of fever and of exercise on metabolism; and so forth, *ad infinitum*. Many a worker on such subjects in a remote sanatorium would feel the moral tonic of the help and association of a central scientific committee. Again, in all public or semi-public institutions there should be a bench in the laboratory where any pathologist, neighbour or visitor, could avail himself of the material either for research or for self-improvement. I attach importance also to the establishment of some connexion between the district medical officers of health and the sanatoriums; but this is a long story.

I am guilty of no extravagance when I suggest that one-third of you who hear me, wittingly or unwittingly, are, or have been, infected with tubercle. Some of us, ailing indefinitely, may have been the innocent means of infection to others, so secretly stalks infection in our midst. Every trustworthy report from sanatoriums—and herein I must compliment our colleagues of Germany on such reports, the last in my hands, and this not the least, being that from the sanatoriums of the Hanse Towns—every such report, I say, emphasises anew the remarkable success of Brehmer's system, on one condition—namely, that the patient be caught at the outset of his disease. Happily for me, it is not within the sphere of this paper to ask what provision is to be made for advanced cases, whether for their own comfort or for the safety of the public, this is a matter of State Medicine; but it is my duty to reinforce your demand that advanced cases, save in a few overwhelming infections, shall cease to occur. There has been much supineness in the matter of early diagnosis—a supineness bred of pessimism, of despair; let us bring the inspiring message of optimism, of

enthusiasm. Let every physician, however modest his sphere, remember that upon his alertness depend the lives of the infected and the stamping-out of infection. The incipient case of to-day is the advanced case of to-morrow. On former occasions I have said that a case presenting the ordinary first stage symptoms of the out-patient room, if for our fathers an incipient case, is in our eyes an advanced case; yet too often still the family practitioner waits till the physical signs are evident to a second year's student. What consultant has not felt his heart sink as, in the so-called incipient case, the "consonating r  le" fell upon his ear? Medical men who have no ear for music ought to distrust themselves a little in auscultation. Not long ago a physician, as honest as he is accomplished, told me that he could not perceive a difference of percussion which I estimated at quite a quarter of a note; he lamented his lack of an ear for music. Early diagnosis depends, however, less upon this detail or that, more upon the cumulative evidence of many indications which the family physician is in the best position to appreciate. The features of the individual do not carry much weight with me, excepting, of course, such acquired features as scars in the neck, or the thick nostrils and upper lip due to the catarrhs of childhood. Many persons of so-called tuberculous aspect never fall victims to the bacillus; many of robust appearance are attacked. Never let muscular strength, ruddy cheeks, or a well-formed chest blind us to canker within.

Whosoever complains of being overwrought, of being "off colour," as the phrase goes, in him suspect phthisis, cough or no cough. Let no hamoptysis, however slight, be set down to a "blood-vessel in the throat"; let no pleurisy, however long ago, be forgotten. In examining the sputum, if any there be, we shall not take the absence of bacilli as an assurance of safety. In young children we may find some occasion of examining vomit for bacilli. If there be no fever, a high mean pulse-rate with low arterial pressure will keep us on the watch, especially if therewith there be some loss of weight, an unusual tendency to sweat and languor after exertion. Indeed, we shall not admit the absence of fever until we have taken the temperature in the rectum every two hours of the 12 of the day, and particularly after exercise. To an  mia, to dyspepsia, to vague pains in the chest, if we shall not give more than their due weight, we must not give anything less. Percussion, which must be made on the bare chest of the patient, sitting on a wooden chair without cushion, must be made with a light finger, and the notes must be estimated not so much by absolute pitch as by an attentive comparison of the two sides. Even if both apices be affected the notes of the two are never identical. I would ask you if comparison of the percussion notes in respiration and in expiration is of importance? The larynx should always be examined, if only for loss of colour. The Roentgen rays, so anxiously tested by Dr. Walsham and others, have not yet proved to be of use in doubtful cases. The spirometer, valuable for comparative records in the various stages of a patient under treatment, is of no use in early diagnosis. Attempts to plot out curves of fever characteristic of tubercle or mixed infections seem not yet to have met with much clinical success. Of tuberculin in diagnosis I have had little experience; in one case, however, it was a great help to me; yet tubercle sleeping in many of us, if not by its use awakened for mischief, might give some ominous answer in its dreams.

The next question I would submit for consideration is that of the mean duration of residence in the sanatorium. The degrees of cure are three—namely, arrest, obsolescence, and *restitutio ad integrum*. To consider this last is to be too curious. Nay, even if we make obsolescence our term for discharge we shall nip sanatorium treatment in the bud, at any rate for the poorer classes. To bring about obsolescence of phthisis, even of the first stage, we need, in my opinion, two winters and one summer at least—say, 18 months—and in saying this I am astonished at my own moderation. In many cases three winters and two summers will be needed. But how many, even in the easier classes, can sacrifice this time without breaking up their careers and abandoning the ties of home? Such, nevertheless, is the advice which for many years I have had to offer to those who have consulted me; and this opinion I must still give if we are to be satisfied with nothing short of obsolescence. But during the last few years, during which time statistics, such as those of Dr. Turban and of Dr. Trudeau, have been given to the world, since we have had to reckon with what is practically possible in the provision of sanatorium accommodation, and

to consider if it be worth while to spend money on a vast scale for cures beyond our compass, my own views have undergone a change. Herein I have been much impressed by the distinction which our German colleagues have drawn between "*wirtschaftliche Heilung und wissenschaftliche Heilung*";—as we may express it in English, between a pathological cure and an economical cure. What is meant by a pathological cure we know, as we know also that the means of such cures are unattainable save by persons of wealth and leisure, and not by all even of these. Keeping our minds fixed upon the first stage—for we will not admit that physicians will continue to let cases drift into the second without sanatorium treatment—it appears that after a certain time patients may be allowed to return to clean homes and wholesome occupations so far improved, and, what is quite as important, so deeply imbued with sanatorium methods, that most of them will hold their ground for some years, and many will ultimately recover. To fix a term for the individual case is, of course, impossible; but, now that large numbers have been dealt with, a mean term may fairly be demanded of us by the paymasters of these resorts. Some sanatoriums put the mean term at three months, which seems to me too sanguine; others put it at six months.

When we try to apply some general rule to the individual case, to estimate for the patient and his friends how far he will fall within the mean or without it, we must be guided by certain individual features. For instance, if fever continue after the first 10 or 14 days the mean duration of residence will be exceeded. How long may fever continue, and yet the patient do well? In view even of an extreme term, is it any use keeping a patient in the occupation of a bed if the fever has not subsided, say, in four or six months?—for we may have 6 or 8 per cent. of such cases. Rapidity and instability of pulse are adverse symptoms. Sugar or albumin in the urine is, of course, of bad omen. Poor feeders do badly. Toppers do badly. Young patients not out of their teens do badly on the whole; and so, again, do patients in the later decades of life. A steady gain of weight is, of course, hopeful, but patients may gain weight while retrogressing in respect of local disease. I have expressed the opinion that tuberculous pedigree does not tell against the case prognosis; but herein Sir William Broadbent differs from me. Pregnancy is, of course, a very unfavourable complication. Gout I regard as a very favourable one. An obedient patient of tranquil temperament has a much better chance than the wayward or fretful. As to physical signs—I have not worked in a sanatorium; but on my fragmentary experience I think that if on admission there were crepitations at one apex these ought to have dried up in a month or six weeks if the patient is to be discharged in three months; at which term the physical signs should have become fairly negative. As to bacilli, these pests seem to persist indefinitely in many patients discharged and otherwise doing well. In bronchiectatic cases, on the other hand, they may not be found. I attach more importance to a diminution of the quantity of the sputum. Upon such data as these I think the chances of the individual case in respect of the mean stay may be calculated, say, after the first month's residence? That the presence of tubercle in other organs is a very grave factor in the prognosis I need not say; cases of slow scrofula with pulmonary complication often indeed do remarkably well, but in most other cases of multiple diseased organs I have had disastrous experience. Multiple deposits in the lungs themselves also in their degree forbid the more sanguine hopes. However, if sometimes we are disappointed by the ill results of a case in which we had looked for better things, on the other hand, it happens, more frequently, I think, that cases in which we had not dared to hope much gratify us by revealing an unexpected power of recovery. Thus the cruel face of Nature may break into a smile.

It is only by means of the kind reception that many sanatorium physicians have given me, and of the free and generous manner in which they have allowed me to share their thoughts, that I shall dare to-day to discuss treatment in sanatoriums. I will begin by quoting the words of him to whom my debt is the greatest—viz., Henry Bennet. In 1866 he wrote of the physicians of his time: "They dare not apply to their patients the ordinary rules of hygiene; they dare not give plenty of animal food; they dare not give fresh cool air day and night; they dare not keep the skin clear and cool by cold or tepid sponging. .... Their patients when they go to health resorts think they ought to take exercise, and they do so. .... They think it did them good

when well, and will do so now when they are ill; but they merely walk themselves into the grave." If I quote no more than this, does not that which I have read tell us how enlightened a forerunner was Bennet in the treatment of phthisis? And now we are tending to drop into the opposite routine of idleness and stuffing. So hard is discrimination. Whatever our treatment, let us first take such order with ourselves that it shall not be treatment of the abstraction Phthisis, but of the individual victim of tubercle bacilli, of which victims no two are identical. Such discrimination means well-paid physicians, and many of them. I repeat, let us not fall into the routine of asylums for the insane, wherein the public authority has always been seeking how far it can reduce the salary for which it can get medical men to apply, and, having got them cheaply, how many patients it can make them attend to. Let not the public act in sanatoriums, as it acts in asylums and hospitals, as if, that is, the public had itself found out how to cure diseases and had engaged a few medical men to carry out its own ideas.

As in other diseases, so in phthisis, the first task in undertaking a cure is to clear up arrears. When the patient comes under care, in most cases at any rate, he has drifted into physiological debt. He has mortgaged his estate, has overdrawn his banking account, has bought raw material at forced prices and paid for it with bills renewable at heavy fines. Our first duty, then, is to straighten the account; and it is astonishing how much is to be done by reducing expenditure, by husbanding profits, and by clearing off arrears. Every patient, febrile or not, should rest for ten days or so until the physician can reckon up the balances. And let it not be forgotten that the stomach, indispensable as it is, indeed, because of its indispensability, needs rest too—that is to say, it must be nursed. To thrust a heap of food into the stomach of a worn or exhausted human machine is to court failure; fortunately, such is the tolerance of the human body the patient is often quit of such an error for 10 days' indigestion and "biliousness," when the food has to be moderated after all. Now I do not often read in the reports of cases, amid their long lists of physical examinations, records of the dimensions of the stomach before and after meals, which I regard as one of the most important of these examinations. In weak and febrile patients the walls of the stomach are almost always lax, so that the food is delayed in the viscus, and tends to ferment there; especially if the secretions of the peptic glands are attenuated; under the internal pressure the organ gives way more and more, and may not recover itself in the hours of emptiness, or indeed, if feeding by frequent snacks is advised, may never become empty. Not long ago I saw such a patient, stuffed on the most modern principles; his medical attendant was annoyed that he positively declined to eat, that he was nauseated, and was losing ground rapidly. On examination of the emaciated body we were able not only to map out but even to grasp a large pendant stomach as full of food as a haggis. How long it had been full I do not know. For the first few days let rest be rest all round, stomach included; then, after the varying dimensions of the organ are known, the food may be increased according to the energy of the individual. Another warning I would give is to watch carbohydrates with care. Feeble stomachs digest these materials with less activity, and they tend to generate flatulence. Man at bottom is carnivorous. I think milk is given too profusely. The bulk of liquid has two dangers: first, it impedes digestion by diluting the gastric juice and distending the stomach—at any rate, in non-febrile cases where liquid is not so quickly disposed of; and, secondly, it adds to the mass of the blood which the heart, often ill-nourished, has to lift. For my part, I rarely find the need of forced feeding—now and then a patient is fastidious, but the secret of forcing the food is to put the patient into open air as cool as he can bear it, and if the cook is a good one the appetite in hopeful cases will come back of itself. On my first visit to Davos, when I found myself at table with 30 weather-beaten people eating like wolves, I exclaimed to Ruedi, "But where are your patients?"

Food has two ends to fulfil: to compensate fever, if, that is, fever be present, and to nourish the body. Feverish patients will dispose of more liquid than the non-febrile; and as in them the stomach is usually relaxed the food must be in frequent small quantities. Gabrielowitch, in a series of careful experiments, has shown that in the phthisical, and not in the febrile only, the weight falls with

surprising rapidity between meals if these are at too long intervals. This fall he finds best marked at nights between supper and breakfast. It would seem, then, that so long a fast, however wholesome for the sound, is not desirable for the sick. As he epigrammatically puts it, "Irritability and sleeplessness are the hunger of the phthisical." When fever has disappeared, and the patient has regained his normal weight, the physician, by close watching of the scales, will be able to return to ordinary meals at the usual intervals. There are now no more arrears to make up, only the balance of waste to repair.

Of alcohol Bennet well said, "Even when it is prescribed medicinally there is always the risk of abuse. It is a double-edged sword." For a few days, occasionally, when the patient flags, when his skin is cool and damp, when his pulse is feeble, when his digestion is slow, and when after meals he is depressed in spirits, it is helpful; as a rule it is not needed. It is our duty, then, as pathologists, knowing that liquorish habits favour tuberculosis, to discourage the still prevalent notion that without alcohol a sick person can never regain strength. There are many lives to throttle out of this cat yet. All patients, without exception, must rest both before and after meals; the latter they remember, the former, which is at least as important, they are apt to forget. Patients liable to vomit food must take their meals in bed. Exercise may be insufficient; indolence may lead to padding with fat rather than to hard condition. Stalled fat cattle are more subject to tuberculosis than the leaner kine on the hillside. The restoration of the heart degenerated by toxins is to be brought about by regulated exercise, and in no part of the treatment is the discrimination of the sanatorium physician more indispensable. On massage I would invite opinions: in former years when more patients remained under home treatment I thought it very beneficial; since the departure of our patients for the sanatorium I have had little further experience of it. I would ask particularly whether massage is inadmissible during moderate fever?

In the earlier days of Davos hydropathy had some vogue, especially the douche. On these means also I would invite discussion. I have found much good in the wet sheet, and the wet pack may be helpful in fever.

The use of gymnastics in the treatment of phthisis is little understood. That in certain phases of disease of the lungs gymnastics must be inappropriate needs no insistence. For instance, he would be a brave man who ordered lung gymnastics in a case of softening or recent hæmorrhage. In phases of softening, again, the risk of suction of septic matters from one part of a lung into another would forbid all exertion likely to cause forcible inspiration. At high altitudes it would seem that the larger volume of the inspirations promotes insensibly an expansion of the lungs too gradual to bring about this peril. In healing stages, when softening has ceased and the lung is drying and laying down protective fibre, may not gymnastics, under supervision as skilled as for cardiac disease, do much to expand and thus to call into healthy function the parts which the tubercle has spared? I seek the answer from those who are dealing daily with these problems.

To admit that there is no drug endowed with specific virtue in phthisis is not to admit that drugs are never useful. For the most part the open air will reduce fever, will prevent sweats—whether due to fever or debility—will promote appetite, and will calm and fortify the circulation. But it is not to be forgotten that during liberal feeding gentle laxatives, and especially an occasional mild mercurial alternative, prove valuable; that a drop of an arsenical solution may settle an irritable stomach, a few drops of strychnine may brace up a slack one, and so on; but I have no faith in courses of drugs, whether antidotal, tonic, or topical, save, of course, in laryngeal cases, which, as the part can be got at, are to be treated locally from the first.

Finally, I must protest against the emptiness of mind which certain reformers would enforce upon their patients. I feel sure that a lack of tranquil occupations and amusements conduces to introspection, and, moreover, is not without grave peril to the moral life. Most of the patients we have to treat depend for their livelihood upon habits of industry; young folks may be sent to a sanatorium at the very time when the habits of life are forming, and it is deeply to be regretted if to the calamity of tuberculous infection must be added a dissipation of those virtues of energy and method upon which our happiness depends. During phases of bodily incapacity submission to the inevitable takes the form of a duty, unfortunate as the loss

of time may be; but vapid hours and aimless days may break up the hardly won discipline of a careful education, if it do not abandon the thoughts to wantonness. The vacuous looks and aimless wanderings of the patients hanging about the precincts of some sanatoriums have impressed me painfully. Vigorous games are rarely suitable; but surely there are occupations, such as gardening, the fine arts, literature, natural history, and quiet handicrafts, which to those free from fever would be beneficial. Perhaps even the visits of teachers in the arts and sciences would not prove so wildly exciting as to throw the population into a fever.

I will sum up the chief questions which I have propounded.

1. Can mixed infections be recognised from fever curves?
2. Can we distinguish between economical (*wirtschaftliche*) healing and complete (*wissenschaftliche*) healing? if so, what is the mean term of residence for the economical healing of early cases?
3. How long in certain active cases, say from 6 to 8 per cent., is a febrile patient to be kept to bed in the reasonable hope of recovery? For instance, in a public sanatorium are we justified in retaining patients who have been confined to bed for six months, five months, or even for four months?
4. What estimates of improvement and what rules of prognosis can be based upon physical signs alone?
5. Is multiple tuberculosis, for instance, in lung and testicle too hopeless a condition for a public sanatorium? How far is it comparable with an equal extent of mischief in one organ?
6. Of what use, if any, is massage?
7. Of what use, if any, is hydrotherapy?
8. Are special pulmonary exercises appropriate at certain stages of progress? and if so, when, and under what conditions?
9. Must we repair the body at the expense of the life of the mind? Can we not give even some educational value to the sanatorium besides the medical drill of it?

## A FURTHER CONTRIBUTION ON ACUTE DILATATION OF THE STOMACH,

WITH AN ACCOUNT OF TWO ADDITIONAL CASES.

BY CHARLES R. BOX, M.D. LOND., F.R.C.S. ENG.,  
ASSISTANT PHYSICIAN TO ST. THOMAS'S HOSPITAL AND TO THE LONDON  
FEVER HOSPITAL;

AND

CUTHBERT S. WALLACE, F.R.C.S. ENG.,  
ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE EAST  
LONDON HOSPITAL FOR CHILDREN.

WE have been led by the perusal of a paper on this subject by Dr. Campbell Thomson<sup>1</sup> and the discussions and letters which have recently appeared on the subject to make this addition to a paper published by us in the Transactions of the Clinical Society of London in 1898. In this paper we tabulated and briefly abstracted 16 cases of this rare and fatal condition and reported two new cases, one by the courtesy of Mr. Walter Edmunds and one which had come under our own observation. Since the paper was published other cases with quite typical symptoms and running fatal courses have been recorded by W. H. Brown,<sup>2</sup> Kirsch,<sup>3</sup> and T. B. Appel.<sup>4</sup> Abstracts of these cases may be found in the *Medical Review* of the same year, with a reference to a case published by Fenger.<sup>5</sup> These and additional cases are also given in Mayo Robson and Moynihan's work on Diseases of the Stomach. An attempt was also made to collect cases of the same disease which did not prove fatal. This was difficult, but we found and abstracted the accounts of five cases which appeared to be instances of the disease in question. Care was taken to exclude all cases in which mechanical obstruction at the pylorus was present. Although it appeared to us at the time that the same train of symptoms might follow in cases of this kind, yet we felt that in discussing the cause, symptoms, and diagnosis of the disease it was better to deal with uncomplicated cases only. The two additional cases which we wish to record are as follows.

**CASE 1. Lacerated wound of the knee-joint; cellulitis of the leg and thigh; ultimate amputation of the limb; acute dilatation of the stomach and of part of the duodenum.**—The patient, a male, aged 29 years, came under observation in 1900 with a lacerated wound of the left knee, opening the joint. A large amount of grit was ground into the wound. The injury was the result of a railway crash, the patient attempting to enter a train in motion and his leg being dragged between the footboard and the platform. The joint wound gave considerable trouble, pockets of pus forming both above and below the joint. Later an arthrectomy was performed and ultimately, on account of severe and repeated hæmorrhage, it became necessary to amputate the thigh. This was about a month after the accident. The patient at the time was extremely collapsed and hardly responded to intravenous infusion of saline fluid, or to brandy or strychnine injections. The bowels were not confined but there was no marked diarrhoea. Unfortunately, no note was made as to the presence or absence of vomiting.

The post-mortem examination was made 17½ hours after death. The only marked visceral abnormality was the condition of the stomach and duodenum. The stomach was dilated and was very prominent. Its upper border was not displaced. Its lower border extended well below the umbilicus. The dilatation was not confined to the stomach, for the first part of the duodenum was dilated to twice its normal size. The dilatation extended to the place where the duodenum came in front of the lumbar spine. The stomach contained a little fluid and some odourless gas.

**CASE 2. Pleuro-pneumonia with severe toxic symptoms; acute dilatation of the stomach and duodenum.**—The patient, a man, aged 24 years, had previously had no serious illness and came of a healthy family. On May 27th, 1901, after playing cricket, he shivered and shortly afterwards noticed a pain in his left side which caused a "catch" on breathing. On the third day of the illness he was admitted to St. Thomas's Hospital, evidently very ill and with a temperature of 104° F. Over the lower lobe of the left lung percussion resonance and vocal fremitus were diminished, the breath sounds were very feeble, and a few crepitant sounds were audible. The abdomen was not distended, the abdominal respiratory movements were present, and the abdominal viscera were apparently normal. On the fourth day of the illness the temperature suddenly fell to 96°, but it rose again the same evening to 102°, and steadily mounted from that time until death when it reached 104°. In addition to the signs mentioned at the base of the left lung, a patch of faint tubular breathing developed in the left scapular region and rhonchi and moist sounds were present over the other parts of the lungs. Profuse and uncontrollable diarrhoea now set in, the bowels acting 15 times on the eighth, five times on the ninth, and 11 times on the tenth day of the disease. The patient was sleepless, complained of severe epigastric pain, and commenced to vomit. He was so collapsed that saline fluid was injected into the subcutaneous tissues, brandy being administered freely and strychnine being injected. Death occurred 11 days from the commencement of the disease. Up to the day before death the urine contained no albumin. No urine measurement was made.

At the post-mortem examination the body was found to be emaciated, the trachea and bronchi contained a large quantity of tenacious mucus, the bronchial glands were swollen, and the left lung was completely pneumonic, the lower lobe being grey and oedematous whilst the upper was still red. The visceral pleura was covered with a thick fibrinous pellicle. The lower lobe of the right lung showed patchy grey hepatisation; the other lobes were congested and oedematous. There was a fibrinous pellicle on the pleural surface of the lower lobe of this side. The heart was not dilated; the cavities of the right side contained tough fibrinous clot, which extended from the auricle to the commencement of the pulmonary artery. There was no endocarditis and no excess of pericardial fluid. The parietal pericardium, however, was thickened and adherent to the superjacent pleura of the left side. The adhesions were recent and "buttery." Inflammation had not spread to the interior of the pericardial sac. The stomach was greatly distended. It lay with its long axis directed downwards and to the right. The lowest part of the viscus was within a few inches of the pylorus and reached the level of a line joining the anterior superior iliac spines. The lesser curvature, after emerging from beneath the liver, ran almost vertically downwards to a point on the right of the mid-line on

<sup>1</sup> THE LANCET, Oct. 26th, 1901, p. 1115.

<sup>5</sup> Clinical Review, 1898.

a level with the umbilicus, then becoming sharply recurved and ascending to the pylorus. The distension *was not* limited to the stomach but involved also the whole of the duodenum, stopping short near the jejunum. The interior of the stomach showed no gross disease; its contents were partly fluid and partly gaseous. The intestines below the duodenum were partially collapsed. The liver appeared to be fatty, the spleen was firm and slightly enlarged, and the kidneys were somewhat swollen, probably as the result of tubal changes. The portal and biliary systems were natural. There was no peritonitis. (For the clinical notes of this case we are indebted to the courtesy of Dr. Hector Mackenzie.)

In our previous paper we particularly drew attention to the fact that the dilatation was not necessarily limited to the stomach but in four of the cases involved the duodenum as well, and in one of these four the first part of the jejunum was said to be also dilated. In both the cases we now record the duodenum was dilated, in one a part and in the other practically the whole of the duodenum being involved. In one of the cases lately recorded by Dr. Campbell Thomson a similar condition of affairs was noted. In the face of this evidence it seems impossible to maintain any longer, as some apparently still do, that the dilatation is due to pyloric spasm. The presence of bile in the stomach contents is additional evidence against spasm of the outlet of the stomach.

One point was very noticeable at the operation on our previous and first case: it was that the stomach was so tensely distended that it actually emitted a musical sound when an attempt was made to pick up its wall. Now it is impossible to believe that a paralytically distended viscus could be placed in a condition of tension so great as this without some mechanical obstructive factor. The question is, How is the obstruction produced? So far as we can gather from literature the advocates of mechanical obstruction of the duodenum incline to one of two views—either the duodenum is kinked by depression of the distended stomach or it is compressed by the root of the mesentery and superior mesenteric vessels which cross it. The advocates of the latter view postulate a *primary* collapse of the intestine and prolapse of the empty coils, such as to cause dragging on the root of the mesentery and superior mesenteric vessels.

We have found by actual experiment on the cadaver that the stomach can be enormously distended by water pressure, with the jejunum cut right across and lying patent in the abdomen. Moreover, the stomach remains thus distended. The same result can be attained after the superior mesenteric vessels and the peritoneal folds in their neighbourhood have all been divided. If, however, by introduction of the finger well behind the distended stomach a little to the left of the mid-line of the spinal column the fundus and posterior wall of the stomach be gently raised the excess of fluid will at once flow freely away from the stomach through the cut jejunum. If the part of the duodenum which lies on the right side of the spine, behind the peritoneum, be first incised, the tense distension of the stomach cannot be produced. We therefore feel justified in assuming that the tense distension is due to actual pressure of the stomach on the part of the duodenum which crosses the third and ascends by the side of the second lumbar vertebra to end in the jejunum.

We would suggest, therefore, that in producing the train of symptoms met with in acute dilatation of the stomach two factors come into play. There is first a paralytic condition of the viscus which leads to distension, and then, at a certain stage the distended stomach actually produces obstruction by pressing on the duodenum on the front and to the left of the spinal column.

The persistence of the vomiting is often held to controvert the idea that the primary lesion is paralytic. It is well to bear in mind the present teaching of physiology on this question. Vomiting may be induced by the injection of tartar emetic into the blood, even after the stomach has been replaced by a bladder, provided that the cardiac orifice has also been removed so that the bladder is actually tied into the œsophagus. If the cardiac orifice be left intact vomiting cannot be induced. Two factors are therefore essential for the production of vomiting: (1) a dilatation of the cardiac orifice and (2) compression of the stomach by the abdominal muscles and diaphragm or in some cases by the diaphragm only. The presence of the power to vomit is not therefore evidence that the stomach is not paralysed.

Acutely distended stomachs usually contain a quantity of gas as well as of bilious fluid. It is quite possible that a

large quantity of this usually, but not always, odourless gas is derived from air which is consciously or unconsciously swallowed, and helps to increase the gastric distension. At the same time saliva is also swallowed, the patient's thirst leads him to drink freely, and possibly gastric hypersecretion also comes into play. When vomiting ceases in cases of acute dilatation of the stomach apparently the abdominal distension becomes extreme.

The early diagnosis of the affection is a point of no little importance. Treatment is apparently futile when the distension becomes extreme. It remains to be seen what can be effected by judicious management in the earlier stages of the affection. A consideration of the recorded cases shows that the recognition of the condition is by no means easy. It has been mistaken for (1) intestinal obstruction, (2) perforative peritonitis, (3) perforation of bowel with encysted abscess, (4) pancreatic cyst, (5) uræmia, and (6) post-anæsthetic vomiting. 1. Of obstruction it doubtless is a form, but of obstruction high up, with obtrusive abdominal signs in the form of gastric dilatation. It must be noted, however, that diarrhoea is present and severe in some cases. 2, 3, and 4. The intense abdominal pain which is usually present, the vomiting, the increasing abdominal distension, and the very marked collapse closely mimic general peritonitis. The position of the percussion dullness in the lower part of the abdomen and right iliac region may on a superficial examination appear to confirm this suspicion. The enormously distended stomach has even been mistaken for an encysted abscess. 5. The incessant vomiting, the partial suppression of urine, the occasional albuminuria, the condition of somnolent delirium which may mark the approaching termination, and the "collapse" temperature which is sometimes but not always present, may well give rise to suspicions of uræmia. 6. In those cases which occur after operations there is a great danger of attributing the vomiting to the anæsthetic and the collapse to the operation. Careful examination of the abdomen in these cases is the only safeguard.

In all cases the readiest way to a diagnosis lies in a knowledge of the conditions under which acute dilatation of the stomach is likely to occur and in a careful physical examination of the abdomen with an attempt to elicit the succussion-splash.

We pointed out in our other paper that the gastric dilatation may not at the onset of symptoms assume the extreme degree seen in the later stages of the disease, and that even a day or two may elapse before dilatation is recognised.

It must be borne in mind that the course of the temperature is variable and is largely influenced by the accompanying disease; a "collapse" temperature is not necessarily present.

The general lines of treatment by strychnine injection, stomach lavage, rectal feeding, and intravenous or rectal saline infusion, have been insisted upon again lately. With regard to an attempt to remedy the obstruction by the postural method we can only say that we have not been able to satisfy ourselves that it is successful in the cadaver, even with the abdomen freely opened, so that the stomach might fall forwards easily. It would appear rational, however, to adopt the right-sided or prone position after syphonage. It might be advisable also to try the effect of atropine injection, this method being believed by some to be of utility in the cardio-gastric crises of diphtheria. In these, however, obvious dilatation of the stomach is a very uncommon occurrence. Should operation be determined upon the ideal procedure would certainly appear to be gastro-jejunostomy, as proposed by Mayo Robson in his remarks on the subject.<sup>6</sup>

## BRIEF NOTES OF A FEW EXCEPTIONAL CASES OF CATARACT EXTRACTION.

BY CHARLES BELL TAYLOR, M.D. EDIN.

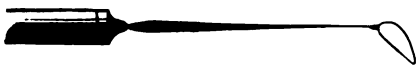

SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

CASE 1.—This patient, from Middlesbro', was born with opacity of the lens in each eye, not the ordinary form of congenital cataract with an opaque centre and clear margin, but with an opacity affecting the lens throughout, slight at first and not sufficient to prevent his learning to read and to write, but gradually increasing

<sup>6</sup> Loc. cit.

until at seven years of age the right eye was quite blind and the left so imperfect that in order to see ever so little he was obliged to hold objects literally in contact with his nose. When I first saw him he had been blind—that is, with only perception of light—for upwards of 35 years in the right eye and the left was not much better, the vitreous was fluid in both eyes, the iris was tremulous, and the lens shared in the general commotion whenever he moved his head. In these circumstances it was clear that any operative procedure would be attended with considerable risk; indeed, he had been treated as an in-patient and as an out-patient at a large ophthalmic hospital and had been strongly advised by one of our most eminent surgeons not to submit to any operation upon his eyes. Nevertheless, as matters were getting worse and he could neither enjoy life nor get his living, I decided to operate upon the right eye; this I did in the usual way, with a small flap upwards, and, contrary to my usual custom, a slight iridectomy. The vitreous drained away the moment the section was completed, the eyeball collapsed, and the lens sank to the bottom of the chamber; I therefore coaxed it out with my wire spoon, an invaluable instrument, since its extreme tenuity enables the operator to assist the exit of the lens without adding to its bulk (see Fig. 1). All went well

FIG. 1.

and the patient recovered without a bad symptom. I therefore repeated the same process on the left eye which also recovered, and this patient now has excellent sight. Here is what he writes on the subject: "I am so thankful to say my eyes are splendid now, I have not had the least pain whatever and can see any distance. I have been taken to church, chapel, and lectures many a time, but never saw the speaker till last Sunday. Things are so different to what I thought they were, it is a new world altogether, oh, dear! after being in darkness for over 37 years and then to recover my sight, I am bewildered and could weep for joy."

CASE 2.—The patient, who was 42 years of age, was struck in the right eye by a piece of steel 15 years ago and the sight of this eye was in consequence completely lost. A year ago the same accident happened to the left eye, and after residence for a month in a large ophthalmic institution he was discharged on the ground, according to his own account, that "it was not possible to do anything for him." The case was certainly complicated and unpromising, but I saw no reason why an attempt should not be made to restore his sight. I therefore operated four times, extracting the lens in each eye and forming an artificial pupil in both. Suffice it to say that he has recovered sight, so good that he is now employed as manager of a large store, a position in which accurate vision both for distance and for near objects is essential.

CASE 3.—The patient, a woman, aged 45 years, lost her right eye 17 years ago from an accidental blow, and recently while nursing a friend's child she contracted purulent ophthalmia, followed by panophthalmitis, shrinkage, and complete loss of the left eye. She had been treated with the utmost care and skill in an ophthalmic institution, and when all hope of restoring sight to the left eye was abandoned she was placed under chloroform with a view to operation upon the right eye, which had been blind so long (17 years). This intention was, however, abandoned by the surgeon at the last moment and on recovery from the anæsthetic sleep she was informed that nothing had been done or would be attempted as the case was hopeless. When I first saw her I found that she was suffering from "cataracta complicata accreta," that the vitreous was fluid, that the iris was tremulous, and that the prospects of restoration of sight by operation were very small indeed. I dared not give an anæsthetic for fear of sickness and excitement, and it was only by a combination of cocaine, holocaine, and what might fairly be called hypnotism that I succeeded in doing a small iridectomy upwards and removing the lens capsule and all entire with iris forceps, leaving a perfectly black pupil, through which she now has excellent vision both for reading and writing and is able to resume her former occupation—that of a teacher of music.

CASE 4.—The patient, a man, aged 74 years, had long suffered from cataract in both eyes; the left had been blind

for years and recently the right had become similarly affected. When I first saw him the cataract had been removed from the right eye by a well-known and experienced ophthalmic surgeon, but with unfortunately disastrous results. The patient's son informed me that before the operation he could see to go about with the operated eye, although the left was quite blind, and I naturally asked, "Why did you have an operation on the best eye when the left, blind so long and with everything to gain and nothing to lose, was inviting interference?" To which he replied that the operating surgeon had said "that the reason why he selected the right eye for operation was because he could use his right hand so much better than his left." I mention this merely to call attention to my bent knife, by which the left eye may be operated upon with the right hand with even greater facility than may the right eye. I operated upon this patient's left eye with the knife in question (see Fig. 2),

FIG. 2.

upwards without iridectomy and am thankful to say that he has now a perfect eye and excellent sight both for reading and for distance.

CASE 5.—The patient, who was blind from cataract in both eyes, was first operated on in Australia, the right eye being selected for extraction, an operation which was performed in the usual way upwards with iridectomy. Unfortunately, everything went wrong. The pupil closed, sight was lost (the retina was said to be detached), and the eye remained in a very irritable condition. In these circumstances it was deemed desirable that he should seek advice in the old country, and he accordingly came over and consulted some of our most eminent metropolitan ophthalmic surgeons, with the result that he was advised to submit to extirpation of the right eye before any operation was attempted on the left, and that he should be then safeguarded by a preliminary iridectomy with an interval of weeks or months before the cataract was extracted from the left eye. He did not see his way to fall in with these suggestions, and as the last surgeon whom he had consulted had told him that circumstances were not favourable for operation and that he had better return home he determined to do so, blind as when he came. At this juncture someone sent him to Nottingham. When I first saw him he was accompanied by a gentleman on whom I had operated for cataract some years ago, and as this gentleman was very anxious to get away the same day I operated upon the patient's left eye at once, extracting in the usual way upwards with cocaine and holocaine and without iridectomy. All went well; he had no pain at the time and none after. There was no prolapse of the iris, the pupil was clear, round, central, and moveable, and the eye (a light grey) beautiful to look upon. It is almost needless to add that he recovered most excellent sight both for reading and for distance. The question now arose, what should be done with the right eye? and some of his friends were very anxious that it should be excised before he incurred the risks of a voyage. No doubt this would have been a prudent course, but I never take an eye out if I can help it, and as the patient had good perception of light I performed a large iridectomy downwards, extracted a mass of capsule and punctured the hyaloid fossa, with the result that he has now very useful sight with this eye, being able to go about with his best eye closed and to read large print (double pica) with a glass.

CASE 6.—This patient came under my care in his eighty-sixth year, suffering from asthma, chronic bronchitis, and constant cough. He was blind from cataract in both eyes and had been advised by an ophthalmic surgeon not to submit to extraction. I operated upon the left eye without misadventure and without iridectomy; there was no prolapse and as the pupil was central and moveable I divided a small piece of capsule and sent him home within 14 days. Later the opening in the capsule closed and I therefore extracted it *en masse* with iris forceps. This operation was followed by an attack of acute glaucoma, which was instantly arrested by sclerotomy and puncture of the hyaloid fossa, and he has now excellent sight both for reading and for distance. The case is worthy of record as the patient, who

keeps a public-house, is a life-long abstainer from all alcoholic liquids.

CASE 7.—This patient also was in his eighty-sixth year when he came under my care. He was then suffering from cataract in both eyes, fully formed on the right eye and commencing on the left. I extracted on the right eye without iridectomy, restoring excellent sight. A decade later he expressed a wish to have the left eye operated on, and I repeated the same process without iridectomy on that eye. As he was in his ninety-sixth year I was anxious that he should be exposed to as little risk as possible and therefore treated him in my private hospital and surrounded him with every care

FIG. 3.

and attention. The day after the operation, however, he got up, dressed, and returned home, where there were no facilities for treatment whatever. Nevertheless, he made an excellent recovery without any prolapse of iris and has now in his hundred-and-first year most excellent sight both for reading and for distance. This case is remarkable and I therefore with his permission present your readers with a portrait of the Nottingham centenarian (see Fig. 3).

Nottingham.

## THE TREATMENT OF OZÆNA BY CUPRIC ELECTROLYSIS.

By EUGENE S. YONGE, M.D. EDIN.,

HONORARY ASSISTANT PHYSICIAN, MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.

It is probable that of all the nasal diseases which, by a somewhat haphazard nomenclature, have been loosely labeled "ozæna," foetid atrophic rhinitis is the one for which the term has most frequently been used as a synonym. When employed in this specific sense it is understood to indicate a disease characterised by a chronic course, by atrophy of the nasal mucosa and sometimes of the osseous structures of the turbinates and by the formation of foetid crusts, and all this without definite discoverable cause.

Until within recent years the treatment of this malady was largely confined to dealing with the troublesome symptoms associated with the disease. It was found that by continued local measures the formation of crusts and the intense foetor could to a large extent be kept in abeyance; and inasmuch as these two disabilities when unchecked were almost as potent to banish the victim from society as was the power given by Kleisthenes to the Athenians, it must be admitted that this was something gained. For a long period, however, no noteworthy advance was made, and although remedies which were said to have healing properties were from time to time suggested it was not until the year 1892 that Jouslain<sup>1</sup> proposed the method of cupric interstitial electrolysis which up to the present date appears to have progressed farthest in the direction of cure. Cheval described the procedure in 1895 and asserted that he had obtained 90 per cent. of cures, the majority of these after a single *séance*, but a committee appointed to investigate the

matter by the Society of Belgian Laryngologists and Otolologists, to whom he had communicated his paper, were far from being able to share his optimism. Bayer,<sup>2</sup> Brindel, Gouguenheim and Lombard,<sup>3</sup> and McBride<sup>4</sup> have all given their experiences of cupric electrolysis, and to the article by the last-named author I am much indebted.

I have had the opportunity of testing the efficacy of this treatment in 15 cases and the details of the method as employed are briefly as follows. The nasal cavities were first thoroughly cleansed by a warm alkaline and antiseptic douche. Cocaine was then applied to the nasal cavity to be treated, and after a few minutes the parts were dried and the electrolysis needles inserted. The copper needle, attached to the positive pole, was passed into the inferior or middle turbinal, usually the former, and the steel needle into the septum. The strength of the current varied, but it was found that from three to 10 milliampères were the most suitable intensities, although currents as strong as 20 milliampères were on a few occasions used. As a general rule, the current was allowed to pass for 10 minutes, and it appeared that no advantage accrued from prolonging the application beyond this period of time. After each *séance* the patient was usually instructed to refrain from syringing the nose until the next examination. The number of applications given depended upon the improvement noted; five *séances* were the maximum.

Although at least one death has been attributed to this treatment I did not myself observe any after-effects which were calculated to give rise to alarm. A patient occasionally complained of slight giddiness and some general disturbance after the application, a few stated that they suffered from neuralgic pains in the teeth and face, and one patient reported that there was some swelling of the face. Two children (aged 11 years and 14 years respectively) each developed a small perforation in the septum as one of the results of the treatment, but in neither case did the event give rise to any permanent inconvenience. With currents ranging from 5 to 10 milliampères there was considerable discomfort and the cocaine appeared to act only in reducing the amount of pain caused by the insertion of the needle; there was, however, a tendency for the unpleasant sensations caused by the passage of the current to become lessened in the course of a few minutes. In analysing my own observations I have divided the cases into (1) those in which the patients were cured; (2) those in which the patients were much improved; (3) those in which the patients were temporarily improved but relapsed; and (4) those in which the patients were not improved.

1. *Cases in which the patients were cured.*—These were two in number.

CASE 1.—The patient was a female, aged 38 years. There was a history of marked crusting and offensiveness for at least 15 years. Examination revealed considerable atrophy of the turbinates and marked crust formation. The patient was given two applications of electrolysis (one in each nostril) at the Manchester Throat Hospital in October, 1899. Since that time she has presented herself at intervals for re-examination and was last seen in October, 1901, but no crust or odour could be detected. She has therefore been free for two years. The patient thinks that her sense of smell has slightly returned.

CASE 2.—The patient was a female, aged 20 years. There was a history of considerable nasal discharge and crusting for several years. Foetor had been marked for at least 12 months. The patient was given two applications in December, 1900. She had not syringed since that date and had not been troubled with foetor or crusting. Now (October, 1901) the nasal cavities are quite free from crusts or odour, although the atrophy of the turbinates persists. She has therefore been free from symptoms for 10 months.

2. *Cases in which the patients were much improved.*—These cases amounted to five, all of whom with one exception (Case 3) were seen in October, 1901, and the reports were made at that date.

CASE 3.—The patient, a female, aged 26 years, came under treatment 18 months ago. When she was last seen she reported that she had had to syringe about four times in three months (as compared with twice daily before treatment). She had been much bothered with crusts in the naso-pharynx; when last seen, however, there was practically

<sup>1</sup> Moure: Bulletin de la Société Française d'Otologie &c., tome xiii., p. 1.

<sup>2</sup> Revue Hebdomadaire de Laryngologie, Mai, 1896.

<sup>3</sup> Annales des Maladies de l'Oreille, November, 1896.

<sup>4</sup> Edinburgh Medical Journal, March, 1899.

no crusting in the nose, but there was marked pharyngitis sicca. The fœtor was very much less; it was, indeed, often absent.

CASE 4.—The patient was a girl, aged 11 years. She had been under treatment about 12 months before. At present she has to syringe her nose two or three times in three months, as compared with daily syringing before treatment. There is said to be now no crusting, but there is slight occasional offensiveness, on account of which the patient still syringes.

CASE 5.—The patient was a girl, aged 17 years. She had been under treatment two and a half months before; there had been no syringing since that time. The nares are at present free from crusts or odour, but there is a small, white, and non-offensive crust on the right side. Although she has been free for two and a half months the treatment is too recent for the case to be fairly considered a cure.

CASE 6.—The patient was a female, aged 23 years. No crusts or odour could be detected, although the syringe had not been used since treatment, two months previously; but the patient states that some crusts of moderate size have been expelled and that slight offensiveness has occasionally been noted.

CASE 7.—The patient was a female, aged 21 years, in whom the last application had been made three weeks before. There had been no crusting or fœtor up to the date of the re-examination, but she is still under observation. This case is so recent that it is perhaps hardly fair to include it.

3. *Cases in which the patients were temporarily improved.*—These cases amounted to six and the patients in all except one reported their condition in October, 1901. Of these the patient in Case 8 has remained free for three months and then relapsed; in Case 9 the patient relapsed after two months; in Case 10 the relapse occurred after several weeks; and in Case 11 after one month. In Case 12 the patient relapsed after 10 days, but she has now only to syringe three times weekly as compared with twice daily before treatment. In Case 13 the patient improved slightly but was lost sight of.

4. *Cases in which the patients were not improved.*—In two cases (Case 14 and Case 15) no improvement was shown; Case 15 was lost sight of after one application.

All the cases were females and in all except one the disease was bilateral. The patients who suffered from marked atrophic pharyngitis gave the most trouble; and it was observed that whilst the treatment applied to one nostril had a beneficial and, so far as could be ascertained, an equal effect on the other, the action of the remedy on the dry naso-pharynx was practically nil. The exact means by which the treatment takes effect is still a matter for conjecture. Possibly fetid atrophic rhinitis is a tropho-neurosis which is benefited by the stimulating effect of the electrical current on the part; on the other hand, it may be that the formation of copper salts at the positive pole is the essential factor.

Whilst I am quite convinced of the relative value of this method of treatment my own small experience leads me to be somewhat diffident of concluding that a permanent cure is to be expected in any but a minority of the cases; and a re-examination, after an interval of several months, of a number of patients who were all too prematurely considered to be cured has impressed upon me that freedom from symptoms for one, two, or even three months does not insure that a patient shall be free from relapse. At the same time, the benefits of cupric electrolysis appear to be so far superior to those of other procedures that it may be looked upon as the best remedy that has yet been found; and although for the victims of "ozæna" it will not repair the shrunken turbinates or restore intact the sense of smell, it will, in a certain percentage of cases, so reduce, or even banish, the tendency to fetid crust-formation that a state of wholesome comfort—the *ultima Thule* of these unfortunate sufferers—is safely reached.

I am much indebted to my colleagues Dr. A. Hodgkinson and Dr. N. C. Haring, and to Dr. H. A. G. Brooke, honorary physician to the Manchester and Salford Hospital for Skin Diseases, for kindly sending me cases suitable for the treatment; and I wish also to express my particular obligation to Mr. A. E. H. Blackburn, of the firm of Mottershead and Co., Manchester, who most courteously rendered me on several occasions generous and valuable help.

Manchester.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### PREGNANCY AND LABOUR IN ONE HORN OF A BILOBED UTERUS; PLACENTA PREVIA.

By CLAYTON A. LANE, M.D. LOND.,

CAPTAIN, I.M.S.; RESIDENT SURGEON, EDEN HOSPITAL, CALCUTTA.

A DUTCH woman, aged 25 years, a primipara, was admitted into the Eden Hospital on July 24th, 1901, in labour, giving the history that pains had begun at 4 P.M. on the previous day, the membranes rupturing at the same time. On admission the pains were feeble and the general condition of the patient was good. On examining the abdomen the bulk of the uterine tumour lay to the right of the mid-line, but just above the pubes; it extended more to the left than to the right. The superficial appearance was one of unusually marked lateral obliquity of the uterus. The position of the child could not be mapped out as the uterus was tenser than usual. The foetal heart-sounds were audible. The external os was not dilated and the presentation lay above the brim. Under chloroform the os was dilated with Hegar's dilators and Barnes's bags and a marginal placenta previa was found on the anterior wall. It may at once be stated that this gave rise to no symptoms at any time. Since the os showed a tendency to close a de Ribes's bag was put in and left for an hour. The pains became feeble and the patient was given 10 grains of sulphate of quinine and in half an hour the pains were strong. The bag was removed and the os was found, admitting three fingers, with the left foot lying just above it. This was brought down and the case was left to nature. The pains, however, died away again. She was given 30 grains of chloral hydrate and 30 grains of bromide of potassium at once and half the quantity of each half an hour later, after which she slept for two hours and awoke with strong pains. An hour later, her pulse being 78 and her temperature 98.8° F., the dilatation was found to be unchanged and the protruding leg was blue and swollen. Accordingly, under chloroform the cervix was digitally dilated and the right foot was brought down. After this by slight traction on the legs during the pains the body was delivered to the umbilicus. The child was sitting astride the cord; this was released and the hands, which were not extended beside the head, were brought down. The head was now gripped by the cervix; forceps were rapidly applied and the head was immediately delivered. The cord was twice round the neck. The placenta followed rapidly and some bleeding occurred, which was checked by massaging the uterus and by a hypodermic injection of 10 minims of ergotin. On examining the uterus with a view to giving a uterine douche it was found that the uterine canal bifurcated in the body of the uterus. The right branch was large and was the one in which the pregnancy had occurred; the left one, though much smaller, readily admitted the finger. Bimanually the uterus was found to be bilobed, the right lobe being of the size of a cricket-ball and the left considerably smaller. The right half of the uterus was douched out. The perineum was torn about an inch; its mucous membrane was sutured with a continuous catgut suture and the skin with silkworm-gut sutures. The child was born asphyxiated and revived with difficulty. The placenta was battledore. The discharge became offensive, though not excessively so, and for this the patient was treated with vaginal douches. Her temperature was as follows: second day, 101°; third day, 101.2°; fourth day, 100°; fifth day, 100°; sixth to eighth days, normal; ninth and tenth days, 104°; eleventh day, 100°; twelfth day, 103°; and subsequently it was normal. On August 13th she was reported to have an offensive discharge, but that removed from the cervix by a swab was sweet. The cervix was split to the fornix on the right side and at this point there was some thickening. The right uterine cornu reached out to the right, extending two inches vertically above the pubes and the inner part of Poupart's ligament. The left cornu lay deeper in the pelvis, was smaller, and was somewhat difficult to feel. The uterus was moveable. On the 18th the thickening beside the cervix on the right side

was replaced by a linear scar. The uterus was less mobile than usual, was bilobed, the right cornu being of about the size of the normal uterus at the same period. The left cornu lay wedged in the pelvis, appearing jammed against the pelvic wall and was seemingly the cause of the want of motility of the organ. The bispinous diameter was nine and a quarter inches and the bisiliac eleven and a half inches. The width of the true pelvis, as estimated by the finger in the vagina, did not appear to be greater than usual.

The chief points of interest in this case seem to be the great reluctance of the cervix to dilate, a well-recognised accompaniment of the condition, and its association with placenta previa. The condition of bilobed uterus seems to be not very uncommon in Calcutta. I find in a search through the register of this hospital that two women with a similar condition were delivered here in 1898; both cases terminated fatally.

I have to acknowledge the kind permission of Lieutenant-Colonel F. S. Peck, I.M.S., to publish this case.  
Calcutta.

#### A CASE OF THROMBOSIS IN A CYSTIC DILATATION OF THE SAPHENA VEIN.

BY GEORGE A. CLARKSON, F.R.C.S. ENG.

THE patient, a man, aged 51 years, consulted me on Feb. 7th, 1901, on account of pain and swelling of the right leg which had commenced on the previous day. He had never had any trouble of the kind before and had enjoyed excellent health all his life. On examination the inner side of the leg from the knee downwards was rather red, swollen, and very tender on pressure. Over the inner tuberosity of the tibia was a hard, exquisitely tender mass of the size of a large walnut, and at the junction of the middle and lower thirds of the leg was a very much smaller thrombus. The intervening vein was tender and thickened but neither enlarged nor varicose. Overlying the patella was a group of varicose veins quite unaffected. Rest in bed with the leg raised, coupled with hot Goulard fomentations and purgation, soon reduced the inflammation, and at the end of a week the two thrombi alone remained, but little reduced in size. On Feb. 14th, under ether, I made an incision five inches in length over the upper thrombus and dissected out a cyst of the saphena vein of considerable size filled with hard clot. The vein was traced some little distance above and below and was ligatured beyond the limit of the thrombus. The lower thrombus was similarly dealt with through a small incision. The subsequent history of the case was quite uneventful. The wounds healed throughout by first intention and by the middle of March the patient was able to return to his work.

I think that this case exemplifies very well the superiority of this form of treatment over that by prolonged rest, which is more commonly pursued, for the following reasons. 1. The patient is effectually relieved from the risk of any dislodgement of clot with its accompanying dangers. 2. It prevents extension of the clot to the deeper veins and main venous trunks. 3. It reduces the necessary rest in bed to a minimum. 4. It leaves the patient afterwards less liable to a second attack. 5. It relieves the surgeon of the difficult task of deciding when, without incurring undue risk, the patient may begin to use the limb.

Leicester.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (ALBANY MEMORIAL).**—The report of the Board of Management for the year ending December, 1900, states that notwithstanding the untoward circumstances of the year no diminution of the hospital's beneficent operations has come about. The full number of beds has been maintained, while the average in occupation has been larger than at any previous time. The total number of in-patients during 1900 was 895, the average number of beds occupied was 183, and the average stay of each patient was 75 days. The cost of each occupied bed was £81 6s. 2d., which shows a serious addition to the figures of the previous year (£76 19s. 5d.). The out-patients under treatment numbered 5959, who gave a total attendance of 36,641. The receipts from all sources amounted to £15,843 19s. 6d. and the expenditure was £18,193 14s. 4d.

### METROPOLITAN HOSPITAL.

#### A CASE OF ENUCLEATION OF PROSTATIC ADENOMATA.

(Under the care of Mr. HAROLD L. BARNARD.)

MUCH of the difference of opinion which exists as to the desirability of treating enlargement of the prostate by "enucleation" depends on the fact that many fail to recognise that only certain forms of enlarged prostate are suited for the operation—namely, the adenomata. The success following enucleation in suitable cases cannot be surpassed by any other method of treatment. For the notes of the case we are indebted to Mr. J. D. Hartley, house surgeon.

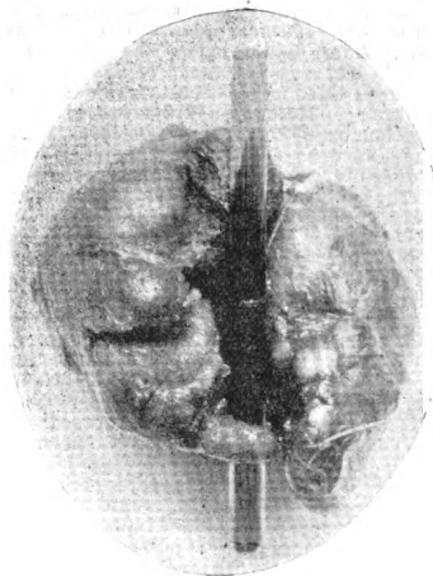

A man, aged 62 years, was admitted into the Metropolitan Hospital on August 14th, 1901, under the care of Mr. Barnard, suffering from enlargement of the prostate. The history was that the patient had had no urinary trouble until five years ago when he had an attack of retention of urine. This was relieved by catheterisation. Subsequently to this on several occasions he suffered from retention, and each time his urine was drawn off by catheter. He passed a quantity of blood with his urine once, three years ago, and during the past year he had frequently passed blood. He had pain on passing urine which was very thick and offensive. The frequency of micturition greatly increased, though he passed but little at a time and the last portion dribbled away. He had great difficulty in starting the stream. The patient was thus suffering from all the troubles incident to enlargement of the prostate and was in such a wretched state that he begged for the operation. He had given up all work and was for the most part confined to his bed.

On admission the urine was found to be alkaline, of specific gravity 1020, full of pus, and of an ammoniacal odour. The residual urine amounted to five ounces. The patient had pain and tenderness in the hypogastric region and in both lumbar regions and down the course of each ureter. By the rectum the prostate was felt to be uniformly enlarged, being of the size of a small orange, and was not tender. The lateral lobes were smooth, rounded, and elastic. A soft, full-sized rubber catheter passed easily into the bladder. The general condition of the patient was fair though his lungs were emphysematous and he had a good deal of bronchitis. He was put on acid sodium phosphate (one drachm to a pint of water) and this he always had by his bedside and drank when he felt so inclined, taking in all about three pints a day. Urotropine was also given in ten-grain doses three times a day. Under this treatment in a week the urine became clear, the pus disappeared, and the smell was lost.

On August 20th an operation was performed by Mr. Barnard, chloroform being administered by Mr. L. Thornley. The bladder was first emptied by a soft rubber catheter and then five ounces of warm boric lotion were injected. An incision two and a half inches long was made in the middle line of the abdomen just above the pubes. When the abdominal wall had been cut through ten ounces more of boric lotion were injected into the bladder and the latter was incised and each margin of the opening was caught up with pressure forceps. The opening in the bladder was enlarged by means of a blunt-pointed bistoury and a pair of vulsulum forceps was passed in. The right lateral lobe was caught and pulled up into the wound. The prostate was then thoroughly explored by the finger; the two lateral lobes projected into the bladder as rounded egg-shaped masses, whilst between their posterior extremities was a pedunculated middle lobe of the size of a walnut. The mucous membrane of the floor of the bladder was incised over the right lobe for about one inch and the forefinger of the left hand was passed into the opening thus made and the growth

was gradually scooped out. Two fingers of the right hand were passed into the rectum in order to keep the prostate up in the wound. After the right lobe had been freed the finger was worked across the middle line and the left lateral lobe was shelled out without further incision. The middle lobe came away with the right lateral lobe. There was a considerable amount of hæmorrhage during the progress of the operation and at the conclusion the bladder was irrigated with equal parts of hazeline and water, thus restraining the bleeding. A long rubber tube bent double with a hole cut at the angle was inserted into the bladder and was stitched to the skin: another suture brought the upper part of the incision together, the lower part being left entirely open. The bladder wall was not sutured, neither was the bladder sutured to the abdominal wall. The wound was dressed with sterilised gauze and wool.

The patient stood the operation well. Four hours later he was dressed. The dressings were soaked through with blood and urine; he had also passed blood and urine per urethram. His bladder was irrigated with warm boric lotion twice a day until the tube was removed. The lotion flowed down one side of the double tube into the bladder and then out through the other limb of the tube. Later he was irrigated through a catheter passed down the urethra. His bronchitis made it necessary to sit him up in bed as soon as he came round from the anæsthetic. His recovery was uneventful; the tube was removed a week after the operation. He was out

Figure, rather less than actual size, showing adenomatous mass enucleated. The glass rod marks the position of urethra and sphincter vesicæ. The adenomatous ring is thin in front but thick behind, where it projected upwards as a middle lobe.

of bed in a chair nine days after the operation and a fortnight after the operation he passed urine from the urethra at will. Three weeks from the operation the suprapubic wound closed and urine passed quite naturally and was sweet and clear; he could hold his urine from three to four hours at a time. He passed it without delay with a good stream and he could project it a good distance. On examination by the rectum the prostate was found to be normal in size and a median cleft could be felt. The part removed (see figure) weighed two and a half ounces and microscopical section showed it to be in structure a simple adenomatous growth.

*Remarks by Mr. BARNARD.*—I do not propose to take any part in the battle for priority which has been raging in another journal. I may, however, state that I was led to operate by the enthusiastic description of Mr. P. J. Freyer and after seeing one of his cases and examining figures of his specimens. In operating I followed as closely as may be the method described in his paper<sup>1</sup> and found it a faithful guide, except perhaps in the matter of hæmorrhage, for my patient lost from 15 to 20 ounces of blood whilst he was on the table

and perhaps another 10 ounces or so the same night. The hæmorrhage was not alarming but it was not insignificant.

There is no doubt that by the method described above the obstructing tumour, which is after all the practical prostate, may be entirely removed, but I do not believe that the anatomical theoretical prostate can be so extirpated. Recently I enucleated a thyroid adenoma of the size of a child's kidney from the right lobe of the thyroid gland. The gaping cavity left was inclosed by the merest shell of thyroid tissue and capsule, which could be seen by the eye but could not have been identified by the finger tip had it been out of sight at the base of the bladder and bathed in blood. So I believe the adenomatous tissue of the prostate is enucleated from the muscular and fibrous capsule and stroma, leaving the urethra and even ejaculatory ducts intact, and probably also the normal glandular tissue thinned out by expansion to a mere membrane. Such an enucleation can be carried out with ease on the cadaver and in this case there is no doubt that the capsule of the gland is left behind. If the plane of cleavage were between the fibrous capsule of the gland and its fascial sheath it would pass through the prostatic plexus and very severe hæmorrhage would be produced, whereas the loss of blood has not been considerable in any reported case of this operation. Moreover, since the urethra and ejaculatory ducts pierce the capsule as they enter and leave the gland, these structures would of necessity be removed with it, and this is not so. In the case reported above the tumour formed a complete collar round the urethra. This collar was broken through in front so as to produce a free end and was then unwound as it was enucleated from around the urethra, leaving that structure isolated in the cavity. The groove of the urethra is clearly seen on the inner surface of the ring of adenomatous material. Another argument in favour of the fibrous capsule of the gland having been left behind is supplied by the fact that my patient had, a month after the operation, as felt per rectum, a normally-shaped prostate which was, however, much smaller than it had been before and was doughy, as though formed of immature fibrous tissue. I have little doubt that as time goes on this will contract.

Among the specimens of prostate glands which I have recently examined and dissected was one in which the enlargement was due to fibrous hypertrophy. The stroma was converted into dense fibrous tissue and no amount of violence was sufficient to enucleate the gland from its capsule. I am bound to admit that this prostate, although enlarged, had not obstructed the urethra in any way, but I should be sorry to find myself embarked upon an attempt to enucleate such a prostate with the tip of the index finger *in situ* and during life.<sup>2</sup> I am not aware of the relative numbers of adenomatous and fibrous enlargements of the prostate which obstruct the urethra, but it will be essential before this operation comes into general use to be able to distinguish the one from the other, as can be done in the case of the thyroid gland.

Whether Mr. Freyer really removes the entire anatomical prostate, as he supposes, does not appear to me of so much importance as that he has brought prominently before the profession an operation which promises to be a radical cure for this common and malignant complaint. When the tumour had been enucleated in my case and the tip of the index finger explored the cavity it was abundantly clear that nothing was left of the prostate but an empty shell which was so thin that the fingers in the rectum and bladder appeared perilously close to one another. All other measures appear pitifully palliative when compared with such a result as this: the painful and unsatisfactory catheter life full of awkward limitations, and punctuated with attacks of hæmorrhage, retention, and cystitis. Castration and vasectomy, at one time so promising and hopeful, now appear to alleviate only, leaving the tumour untouched, although the prostate and bladder are less irritable and less subject to attacks of congestion and cystitis. It is a fundamental principle of surgery that when a tumour obstructs a passage the patency of which is essential to the continuance of life that tumour should be removed forthwith: or if this is not possible some short circuit must be established. The latter method is scarcely ever applicable to urinary surgery. When thyroid adenomata press on the trachea or œsophagus the surgeon loses no time but enucleates them or extirpates half

<sup>2</sup> Since the above was written I have attempted to remove another enlarged prostate and found it fibrous. No effort was sufficient to enucleate it and all that could be done was to cut away the obstructing portions of the prostate. The patient is, however, doing well.

<sup>1</sup> Brit. Med. Jour., July 20th, 1901.

of the thyroid gland. When pelvic tumours press upon the rectum, ureters, or urethra it is considered a clear indication that they should be at once removed. By a similar reasoning I believe that in the near future, when adenomatous enlargement of the prostate has once caused urethral obstruction, no time will be wasted whilst the bladder, ureters, and kidneys become dilated, whilst sepsis spreads throughout the urinary tract, and whilst the patient is worn out by pain and hæmorrhage, toxæmia and renal inadequacy; but at once, while he is strong, the entire tumour will be enucleated and the urethra permanently freed from obstruction.

The use of acid sodium phosphate ( $\text{NaH}_2\text{PO}_4$ ) in order to render the urine acid was first suggested by Dr. Robert Hutchison who has not, I believe, published his results. This drug is far more efficacious than boric acid or ammonium benzoate. It is best administered as described above, one drachm to a pint of water flavoured according to taste and taken as a beverage during the entire day. In excessive doses it only purges. I can speak very highly of its results in ammoniacal cystitis especially when combined with urotropine.

### SUSSEX COUNTY HOSPITAL, BRIGHTON.

#### THREE CASES OF TRAUMATIC TETANUS RECOVERING UNDER ANTITOXIN.

(Under the care of Dr. E. MACKEY.)

FOR a determination of the exact value of the antitoxin in the treatment of tetanus we need the notes of even more cases than have been already published, and for the purpose of statistics series of cases occurring in the same institution or under the care of the same surgeon are of especial value, for on the one hand the method of treatment is likely to be more uniform, and on the other all the cases which have been under treatment will be considered. For the full value to be obtained from the record of any case of tetanus it is necessary that the following points should be noted. 1. It is always well that the diagnosis of the disease should be confirmed, if possible, by the discovery of the bacillus in the wound. 2. The incubation period should always be stated, for at present this is the most definite guide which we possess for the forming of a prognosis early in the disease. The longer the incubation period the more probable is it that the attack will not be severe. 3. The source of the serum should be mentioned, for at present there is little doubt that there are great differences between the activities of the various sera. 4. The exact doses administered and the time when given should be stated. It must not be forgotten that the use of antitoxin does not render useless the administration of sedatives. These should still be given and will afford much aid in controlling the spasms. The local wound must be rendered thoroughly aseptic, and should this be difficult excision or amputation may be required. The importance of this local treatment is obvious when it is remembered that the bacillus lives only in the wound and does not enter the circulation, its toxins only being absorbed. As to the dose of antitoxin, in most cases from 30 to 100 cubic centimetres or thereabout have been administered, but a case was reported last year<sup>1</sup> in which Dr. Sydney H. Long of Norwich administered 625 cubic centimetres of serum hypodermically and 55 cubic centimetres by the rectum. The patient thus treated recovered. It cannot be laid down at present with any certainty what is the maximum quantity that should be administered, but obviously we should not risk poisoning the patient with the remedy. The following three cases form a series and are carefully recorded; they are therefore of great value in assisting our knowledge of the treatment of this disease. Dr. Mackey is to be congratulated on the recovery of all his three patients, and we shall hope to have reports of any further cases, so that the series may be extended. Mocheowitz<sup>2</sup> considers that the antitoxin treatment has reduced the mortality of tetanus from 90 per cent. to 40 per cent., but most medical men who have examined this question will hesitate to endorse this statement.

CASE 1.—A boy, aged 15 years, a gardener, was admitted into the Sussex County Hospital on Oct. 28th, 1899, having crushed his left little finger between a barrowful of manure and a wall three weeks before. About one week previously

(i.e., after an incubation of about a fortnight) he felt back-ache and difficulty in opening the mouth and had been getting worse daily. On admission he lay extended on his back, which was somewhat rigid and painful; the head was retracted; the face was flushed and sweating, with marked "risus"; the mouth was tightly closed but could be opened sufficiently to drink and to speak. The crushed nail was loose and dirty; it was removed and its bed was cleaned and carbolicised. The temperature was 99° F., the pulse was 76, and the respirations were 20. At 8 P.M. 10 cubic centimetres of anti-tetanic serum (which was obtained from the British Institute of Preventive Medicine) were injected, with antiseptic precautions, into the abdominal wall by Mr. A. C. Jordan. On the 29th the patient had dozed or slept with occasional attacks of general spasm and starting and pain in the right hand and back, rigidity, and sweating. He had taken well feeds of milk of from four to five ounces, with egg and two drachms of brandy and also some beef-tea. At 11.30 A.M. 12 cubic centimetres of serum were injected. At night one dose of chloral and bromide was given because of rigidity, pain, and spasm (when a door banged). On the 30th he was no worse. At 11.30 A.M. 12 cubic centimetres of serum were injected. There was no fever. The pulse was good. The bowels were slightly opened. One dose of chloral and bromide was given at night. On the 31st the symptoms continued, but in shorter attacks of rigidity, retraction, sweats, pain in the chest, "phlegm" in the throat, &c. He took the feeds and passed urine freely. At 11 A.M. 13 cubic centimetres of serum were injected. The temperature was 97°. A full dose of chloral and bromide was given at night, but he had a severe attack of rigidity and arching about two hours after. On Nov. 1st there was less "risus" but more frowning. He had bitten his tongue. At 10 A.M. 13 cubic centimetres of serum were injected. Pain in the right side and leg was present. The patient was excited and there was difficulty in feeding. Chloral was required in the morning. The bowels were not opened; compound mixture of senna was given. On the 2nd he held his ground, but he had pain in the left leg. At 11 A.M. 12 cubic centimetres of serum were injected. He required chloral at 2 P.M. and again in the night for pain in the left leg which caused him to cry out. He was quieter afterwards. On the 3rd the patient was better. He could open his mouth and asked questions. There was less rigidity; 10 cubic centimetres of serum were injected. There was occasional spasm. Chloral was given at night only. On the 4th he was distinctly better; 12 cubic centimetres of serum were injected. The bowels were opened. He had one dose of chloral. On the 5th he was progressing favourably, but had pain in the leg, which was relieved by liniment; 11 cubic centimetres of serum were injected and he was given one dose of chloral. The pulse ranged from 80 to 88. For two days he had been free from spasm. An acid and malodorous sweat was present; 11 cubic centimetres of serum were injected. On the 7th a red blush was present over the joints of the shoulder, elbow, and knee, and between the shoulders and on the back. This was irritable till bathed with boric lotion. On the 8th the rash was present also on the abdomen, one patch being much raised, and on the cheeks and the forehead. It had faded on the elbows and had disappeared from the legs. The patient had had a quiet night and could put out his tongue, which was raw. On the 9th the rash had faded. He complained only of sore-throat and some pain in the neck and left leg, and some rigidity of the abdomen. On the 21st the patient sat up and on the 28th he was convalescent. Altogether he had had 10 injections, making a total of 116 cubic centimetres of serum.

CASE 2.—A man, aged 49 years, a bricklayer, was admitted into the Sussex County Hospital on June 29th, 1901, supposed to be suffering from sunstroke; no history of any wound was given. He was said to be a heavy drinker, but he had never been ill till five days before, when he felt pain all over, especially in the shoulders and groin. There was no vomiting but much sweating. He could not now open his mouth wide and his legs were rigidly extended; he could not flex them and movement caused general spasm. The knee-jerks were excessive. The pulse was 112, the temperature ranged from 99° to 100° F., and the respirations were 28. The tongue was furred. He was given castor-oil, and morphia was injected hypodermically. On the 30th the patient had had several attacks of spasm during the night. The back was rigid. (Bromide with phenacetin was given.) He was sweating profusely. The pulse was dicrotic. On July 1st a

<sup>1</sup> Brit. Med. Jour., Nov. 24th, 1900, p. 1495.

<sup>2</sup> Annals of Surgery, October, 1900.

whitlow was found and opened on the finger of the left hand, the result, the patient said, of a splinter from his barrow which pierced his hand three weeks previously (= incubation of about a fortnight). In the evening 10 cubic centimetres of anti-tetanic serum (which was obtained from the Jenner Institute) were injected by the house physician (Mr. P. Foster). The bowels were opened after calomel had been given. On the 2nd there had been much spasm during the night and till 4 A.M., when a further 10 cubic centimetres of serum were injected and the patient became easier. The finger was freely incised and fomented with perchloride of mercury lotion (Mr. A. H. Buck in consultation). 10 cubic centimetres of serum were injected at 10 A.M. and also at 10 P.M. The patient was moved to a special quieter ward. On the 3rd he had passed a good night excepting for three bad spasms. He was now comfortable and could open his mouth better. Ten cubic centimetres of serum were injected at 2 P.M. and eight cubic centimetres were injected at 10 P.M. He had had four severe and eight slight spasms, but he was easier after the injections. He had milk diet with three ounces of brandy in the 24 hours and three doses of bromide and chloral mixture. On the 4th he had passed a fair night, there having been four spasms. Two doses of sedative were given and 11 cubic centimetres of serum were injected at 10 A.M. He was sweating freely and had many severe spasms of the whole body. He was excited even by speaking but between whiles he had been easier. The finger has been frequently fomented and now ached and smarted much. He had taken liquid food and water freely and three doses of sedative were given during the day. Ten cubic centimetres of serum were injected at 10 P.M. On the 5th he had passed a fair night and he was "greatly relieved by the injection." He was given a sedative also at 10 A.M. Six cubic centimetres of serum were injected and again at 10 P.M. He was comfortable all the day. On the 6th he had had a good night as to spasm, but there had been a tendency to collapse. Medicine was omitted. At 10 A.M. five cubic centimetres of serum were injected. He had a good day. Spasms occurred but were slight and were brought on by any disturbance. On the 7th he had passed a fair night, but at 9 A.M. severe spasms commenced, two occurred in succession and in half an hour three more with slighter ones between. At 10 A.M. the medicine was resumed and seven cubic centimetres of serum were injected. Seven severe spasms occurred before 8 P.M. when they were controlled by hypodermic injections of morphia and sedative medicine and eight cubic centimetres of serum. There was a tendency to collapse. The medicine was stopped and the fomentations were continued. On the 8th the patient passed a better night. Five cubic centimetres of serum were injected at 10 A.M. and he passed a very comfortable day. There was an urticarial rash on the abdomen. He had a good night till 5 A.M., when suddenly he woke with severe spasms, followed by 10 other attacks and some collapse and cyanosis. A quarter of a grain of morphia was injected hypodermically and medicine was given. The attacks were controlled and eight cubic centimetres of serum were injected at 10 A.M. on the 9th, after which only one slight spasm occurred and the patient passed a comfortable day. The rash was fading. The temperature ranged from 97° to 98° and the pulse from 100 to 112. The patient passed a good night. On the 10th in the morning at 10 serum (five cubic centimetres) was injected for the last time. The hand was in a bath of biniodide of mercury (1 in 500) for eight hours, but it caused pain and vesication, so borie ointment was substituted. From this date he gradually convalesced, requiring treatment for occasional collapse, but he was discharged quite well on July 31st, having had 16 injections, the total quantity of serum used being 131 cubic centimetres.

CASE 3.—A young man, aged 19 years, a bricklayer, who was employed in the same works as the patient in Case 2, was admitted to hospital on June 29th, 1901, having run a splinter from the *same barrow* under the finger-nail of the left hand on June 14th. This came out one week later, having caused no pain worthy of notice. On the 24th (i.e., after an incubation of 10 days) he felt tightness across his chest and general spasm, with hardness and contraction of the abdominal muscles, which had since spread to the legs and neck, not much affecting the jaws till the day of admission, when he could not open his mouth well and had risus sardonicus. The tongue was foul, the temperature was 100° F., the pulse was 96, and the respirations were 24. The knee-jerks were exaggerated and a tetanic condition with some opisthotonos was readily induced, accompanied

by pain and profuse sweating. On the third finger of the left hand the scar of injury was healed; it was not tender. There were large acne pustules on the forehead. A quarter of a grain of morphia was injected hypodermically and he was given castor oil as well as bromidia at bedtime. On the 30th there was less pain but recurrent spasms were present; 10 grains each of bromide and chloral with five grains of phenacetin were given every six hours. On July 1st there was much groin pain, also retention of urine, requiring the use of the catheter (this and subsequent cystitis were possibly accidental complications from a neglected gleet). Ten cubic centimetres of serum (obtained from the Jenner Institute) were injected by Mr. Foster. During the night spasm was severe and the patient was "light-headed." On the 2nd 10 cubic centimetres of serum were injected at 4 A.M. Later Mr. Buck saw him in consultation. The scar was opened and dressed with carbolic (a mercury-biiodide bath was ordered but the hand could not be kept in it); 10 cubic centimetres of serum were injected morning and evening. On the 3rd the spasms, which were better through the day, recurred, with opisthotonos and some pleurosthotonos in the evening; 10 cubic centimetres of serum were injected in the morning and eight cubic centimetres in the evening. Calomel and castor-oil were also given. The patient took liquid food well; only one ounce of brandy was given per diem. On the 4th during the night he had several severe spasms on waking. The tongue was bitten. Eight cubic centimetres of serum were injected in the morning and 10 cubic centimetres at night. The symptoms were less severe during the day, but chest pain and much sweating were present. On the 5th during the night there were much twitching of the hand and choking on swallowing, but these were relieved after the injection of serum, eight cubic centimetres being injected in the morning and six cubic centimetres in the evening. Through the day the patient was sleepy and more comfortable and was able to extend the legs without rigidity and to open the mouth. He had a comfortable night. Five cubic centimetres of serum were injected on the morning of the 6th. On the 7th there had been much pain in the legs during the night. No injection was made on this date; spasms were present, but were slight in character. The bladder symptoms were becoming more troublesome. The urine was ammoniacal with phosphates. On the 8th he was going on well but for "stiffness." From five to 10 grains of urotropine were given in the morning. The finger was still being fomented with antiseptics. Some faintness was experienced on moving. On the 10th slight spasms occurred on any disturbance. Five cubic centimetres of serum were injected. Bromic acne was now extensive on the forehead and the bromide was stopped and the pustules were opened. The bladder was washed out. The stiffness was said to be relieved by the last serum injection. Solid food was taken. The patient got up on the 12th. On the 13th he was better, but some spasm occurred. Five cubic centimetres of serum were injected. The bladder was washed out daily. On the 17th a whitlow on the right hand was opened. On the 19th there was much blood on washing out the bladder. Urotropine had been continued up to this date, but was now omitted. On the 24th the cystitis was better. The urine was acid. The patient was able to walk out. On the 31st he was discharged well, having had 13 injections, 105 cubic centimetres of serum being used.

*Remarks by Dr. MACKEY.*—The above cases are not selected for publication simply because they recovered: they are all that have come under my care since the antitoxin treatment was established, and I think that their evidence should be added to that which has now accumulated for and against. They may be judged by their incubation period to be of the milder type, but even of such the average mortality has been put at 25 per cent.<sup>1</sup> The impression made on those who watched these cases was of distinct antidotal power exerted by the serum, and although, as noted by others, the spasms seemed to be sometimes increased for a time they were afterwards lessened, and sometimes were relieved markedly and quickly; also, they returned more than once on suspension of the injections and were again mitigated on resuming them. The amount of sedative given was not large and could only be considered as saving fatigue and distress, not as curative; the good nursing and nourishment (of which only brief details are indicated) may be credited with a larger share of the recovery; several times there was imminent danger from collapse.

## Medical Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

*Investigations of the Intracellular Constituents of the Typhoid Bacillus.—Hæmolysins of Bacillus Pyocyaneus.—Isotonic Culture Media.—Proteolytic Enzymes of Fibrin.—So-called Mucous Intestinal Cast.—Products of Splenic Proteolysis.—Artificial Preparation of  $\beta$ -Hydroxybutyric Acid of Urine.*

A LABORATORY meeting of this society was held on Nov. 5th at the Jenner Institute of Preventive Medicine, Mr. WATSON CHEYNE, the President, being in the chair.

Dr. A. MACFADYEN and Mr. A. ROWLAND communicated a paper on the Investigations of the Intracellular Constituents of the Typhoid Bacillus. They then demonstrated the method of obtaining the intracellular constituent and finally recorded some results already obtained as regard the immunity conferred by injection of the intracellular constituents.

Dr. G. F. PETRIE read a paper on the Hæmolysins of Bacillus Pyocyaneus. He pointed out that results in hæmolytic experiments would be of greater value if a more definite system of examination were carried out. A considerable margin of possible fallacy was presented when the results were positive. With a view to lessening the risks of misinterpreting results it was recommended to use a solution in which the osmotic pressure was greater rather than less than that of the contents of the corpuscles. Again, the use of defibrinated blood was to be deprecated. Absolutely fresh unclotted blood was preferable as liable to introduce less chance of fallacy in the results. Definite percentages of the hæmoglobin to be tested were placed into test-tubes of equal size and equal amounts of blood were added by means of calibrated pipettes.

Dr. A. HARDEN read a paper on Isotonic Culture Media.

Dr. S. G. HÉDIN gave a short account of the Proteolytic Enzymes of Fibrin.

Mr. T. B. LEATHES gave an account of the So-called Mucous Intestinal Cast—Mucous Colitis. He said that the casts obtained from cases of Mucous Colitis were not composed of mucin, for they were insoluble in water and in weak alkali. If, however, the cast was treated with an alkali it went into solution. If the cast was left for some days in weak alkaline solution it was dissolved. This solution, however, gave none of the proteid reactions. If the cast was treated with weak acid the solution which resulted would reduce Fehling's solution and therefore it was probable that some glucosin was present. All the evidence seemed to point to the fact that it was not a proteid.—Dr. LESLIE EASTES said that he had investigated several of these cases chemically; he thought that the body was more nearly allied to keratin than to mucin. The cast contained a large number of other cells and leucocytes and these were held together by a mucin-like body. Blood was often present and some of the products gave rise to the chemical tests.—Mr. LEATHES, in reply, said that though the solubility of the substance suggested keratin yet it gave no sulphuretted hydrogen reaction, and therefore he was of the opinion that it was not keratin.

Mr. LEATHES then made a short communication on the Products of Splenic Proteolysis.

Dr. A. MACKENZIE read a paper on the Artificial Preparation of  $\beta$ -Hydroxybutyric Acid of Urine.

**NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.**—On Oct. 23rd, at the Dispensary, Broad-street, Nottingham, the inaugural address for the winter session of this society was delivered by Dr. Risien Russell on the Value of the Tendon-jerks and Superficial Reflexes in Diagnosis. Dr. Russell first called attention to the value of the plantar reflex and tendo Achillis jerk in diagnosis. The former had received a large amount of attention in this country as well as abroad, but very little attention appeared to have been paid in this country to the state of the tendo Achillis jerk as an aid in diagnosis. After referring to the significance of the alteration of the plantar reflex known as "Babinski's sign" or the "extensor response," from the presence of which a lesion of the pyramidal system might be inferred,

he pointed to certain fallacies that had to be avoided, and in support of the value of the phenomenon he quoted three cases from among many in which the "extensor response" had been a great help to him in arriving at a correct diagnosis. The state of the tendo Achillis jerk had been regarded as of especial value in the diagnosis of early tabes and in the differential diagnosis of real from hysterical sciatica, and he could confirm the statements that had been made by neurologists on the continent and in America with regard to the significance of alterations of this jerk. It was especially in cases of tabes in which the knee-jerks were still preserved that loss of the tendo Achillis jerk had proved of service in the diagnosis of this disease. In sciatica the tendo Achillis jerk was commonly abolished on the affected side, whereas this was not the case in hysterical sciatica. As an illustration of the way in which the tendon-jerks assisted in the separation of one form of organic disease of the nervous system from another he quoted cases with atrophy of the muscles of the upper limbs in which the state of the tendon-jerks went far to establish a correct diagnosis. This afforded him an opportunity of indicating the significance of the jaw-jerk and of pointing to its value in the differential diagnosis of cases such as those to which he referred. Finally, he dealt with the help to be obtained from the tendon-jerks and superficial reflexes when attempting to localise the exact situation of a lesion of the spinal cord. He also referred to the fact that the state of the tendon-jerks of the lower limbs served to indicate the degree of severity of a lesion of the spinal cord above the level of the lumbar enlargement. In incomplete transverse lesions, such as commonly resulted in myelitis, there was ankle clonus and the knee-jerks were exaggerated, whereas with complete transverse lesions, such as were usually caused by fracture-dislocation of the spinal column, there was no ankle clonus and the knee-jerks were abolished. A satisfactory explanation of why there should be this difference had been supplied by the results of Sherrington's experimental observations, which made it clear that augmentor influences passed from the ponto-cerebellar region to the spinal segments to maintain muscle tonus. Incomplete transverse lesions of the spinal cord, while sufficient to prevent the inhibitory influence of the cerebral centres from reaching the spinal segments, still allowed the augmentor influences to reach them, whereas in complete transverse lesions the augmentor influences were also cut off and the spinal segments in man did not possess sufficient autonomy to be capable of preserving muscle tonus in the absence of the augmentor influences from above. A case had recently been recorded by Mills in which there was ankle clonus while the knee-jerks were absent, a rare event in that only ten similar cases could be collected from the literature on the subject. This indicated a limited lesion in the lumbar cord and one of the affections suggested that might possibly have given rise to this combination was disseminated sclerosis; but highly probable as it seemed, in a large experience of this disease Dr. Russell had only met with two cases in which the diagnosis seemed likely and in which the knee-jerks were absent. He would always hesitate to diagnose disseminated sclerosis in a case in which the knee-jerks were absent, although such a state of things was, of course, possible. The paper was illustrated by lantern slides of the various morbid conditions to which reference was made.

**LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Nov. 1st, Dr. A. G. BARRS, the President, being in the chair.—Dr. James Braithwaite read a paper on a Possible Factor in the Causation of Cancer, in which he stated his belief that probably an excess of salt in the diet along with either an unnecessary amount of food, and especially meat, or non-use of the nutrient supplied to the tissues, as in old age and in organs such as the womb and breast, was the cause of cancer. The excess of salt, however, was the necessary factor. This was illustrated by the comparative exemption of certain people and animals. Haviland's map of cancer in England was explained by the diet of the people, which varied with the kind of farming, and the farming with the geology. Cancer houses were also explainable on this hypothesis, which Dr. Braithwaite thought to be contradicted by no known facts about the disease. At the same time, he did not consider the theory proved. It was merely a matter for consideration and experiment.—In the discussion Dr. E. F. Trevelyan said that Dr. Braithwaite had brought forward no

satisfactory evidence to show that salt was in any sense even a contributory factor in the causation of cancer. On the other hand, he thought that more systematised efforts than hitherto should be made in order to throw light on the etiology of this ever-increasing disease. Such an object would, in his opinion, be best promoted by the establishment of a league against cancer which should collect evidence respecting all aspects of the question, indicate the more profitable lines of research, and perhaps provide the necessary means to young workers in this pressing field of investigation.—The President, Mr. P. J. Cammidge, Dr. T. Churton, Mr. J. W. Draper, and Dr. G. E. Young also joined in the discussion, and Dr. Braithwaite replied.—Mr. Lawford Knaggs read a paper on Inflammation in Growing Bone arising from Cartilage. Special attention was directed to the predisposing influence of ligament strain and tendon pull or of injury at the juxta-epiphyseal line up to complete separation. The consequences were one of the following: (1) acute periosteal abscess, (2) acute osteo-myelitis, (3) acute septic arthritis, (4) separation of an epiphysis, or (5) acute deep-seated abscess. Each of these subjects received separate notice and nearly all the points were illustrated by lantern slides from specimens. It was suggested that otorrhœa and mastoid abscess not infrequently resulted from this disease in infants less than one year old, before which time the temporo-squamosal suture was occupied by a disc of cartilage which was to all intents and purposes a conjugal cartilage. The immunity of bones developed in membrane was attributed to the absence of the epiphyseal cartilage and this juxta-epiphyseal area.—Mr. H. Littlewood mentioned a case where the path along which infection had spread to the joint was the tendon of the popliteus muscle.—Mr. Pridgin Teale also took part in the discussion and Mr. Knaggs replied.—The following cases, pathological specimens, &c., were shown:—Dr. A. L. Whitehead: A Successful Case of Temporo-sphenoidal Abscess.—Mr. J. Holmes: A Hunting Emergency Case.—Dr. A. Bronner (Bradford): (1) Recent Cases of Extraction of Senile Cataract without Iridectomy; and (2) Apparatus for the Treatment of Dry Catarrh of the Middle-ear by Suction.—Dr. T. Wardrop Griffith: (1) Traction Diverticulum of the Oesophagus; and (2) two examples of Specific Ulceration of the Palate in Children.—Dr. E. O. Croft: Specimen of Primary Cancer of the Labium (Growth and Microscopical Section).—Dr. E. Ward: A Tuberculous Testis.—Mr. Littlewood: (1) Osteoma of the Upper Jaw; (2) two specimens of Epithelioma of the Upper Jaw; and (3) Ovarian Tumour with Twisted Pedicle removed from a patient seven months pregnant.—Mr. Mayo Robson: A case of well-marked Charcot's Disease of the Knee.—Dr. J. B. Hellier: Cystic Myoma Uteri removed by Abdominal Hysterectomy.—Mr. B. G. A. Moynihan: Two cases of Spina Bifida, one Cervical and the other Lumbar, treated by Excision of the Sac.—Mr. W. H. Brown: Ossification of the Pyramidalis Muscle after Suprapubic Cystotomy.—Dr. Trevelyan: A case of Raynaud's Disease with Marked Trophic Changes in the Finger-ends.

**MIDLAND MEDICAL SOCIETY.**—The annual meeting of this society was held at the Birmingham Medical Institute on Oct. 16th, Mr. Jordan Lloyd, the President, being in the chair.—Mr. A. Elmslie Crabbe was elected a member of the society.—The following officers were elected for the ensuing session:—President: Mr. Arthur Oakes. Treasurer: Mr. John Garner. Secretaries: Mr. Christopher Martin and Dr. James W. Russell. Members of council: Mr. W. F. Haslam, Mr. Newton, Mr. E. B. Whitcombe, and Dr. Wood White.—The first ordinary meeting was held on Oct. 30th at the Birmingham Medical Institute, Mr. Oakes, the President, being in the chair.—Dr. M. S. Maclean, Dr. I. L. McNeill, Dr. J. T. Hewetson, Dr. J. R. Charles, and Dr. James E. H. Sawyer were elected members of the society.—The following specimens were shown:—Mr. Gilbert Barling showed a male patient, aged 48 years, upon whom he had performed Albert's Gastrostomy five and a half years previously for what was then believed to be malignant disease of the oesophagus. At the present time the man was able to follow his occupation as an edge-tool maker. He looked fairly well and vigorous and wore in the gastrostomy opening a tube of five-eighths of an inch diameter through which he was able to introduce foods of all kinds if finely divided, and there was practically no leaking at all. There was a hernia through the weakened abdominal wall where the stomach was brought through the left rectus, but this caused no inconvenience. The lapse of time having shown that the stricture was not malignant it was proposed to make an

attempt to dilate the stricture from below, and if this succeeded to close the gastric opening.—Dr. F. Edge showed a patient upon whom he had performed Oöphorectomy for Recurrent Inoperable Cancer of the Breast. The left breast was amputated on April 10th, 1900. On Oct. 17th the pectoral muscles were divided and the glands were found to be shotty above the clavicle and on the vessels at the root of the neck. In February, 1901, the right breast and right axillary glands became involved. On March 10th oöphorectomy was performed per vaginam. On Oct. 30th the glands and breast lumps were quite soft and had practically cleared up. The weight increased two stones and the general well-being was much improved. Thyroid extract had not hitherto been given, but Dr. Edge now intended to make use of it.—Dr. J. G. Emanuel showed a case of Saccular Aneurysm arising from the transverse part of the arch of the aorta. The specimen was from a soldier who had contracted syphilis in India three years before the symptoms of aneurysm developed. He died 15 months after his first symptom from pressure on the trachea.

**SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Oct. 24th, the President, Dr. C. H. Willey, being in the chair.—Mr. R. J. Pye-Smith showed a case of Unilateral Congenital Dislocation of the Hip which he had shown last February, to illustrate the results of treatment. The displacement had been reduced by Lorenz's method of manipulation under an anæsthetic and the hip had been kept for nearly four months in a plaster-of-Paris case. The deformity and limp had now disappeared and a second skiagram showed practical symmetry.—Mr. Edward Skinner showed specimens from a case of Cancer of the Lung.—Mr. E. J. Scolah exhibited microscopical specimens of Bronchial Glands, Liver, Spleen, and Kidney from a case of Lymphadenoma shown last session.—Dr. A. J. Hall showed the following cases: 1. Primary Spastic Paraplegia in a man, aged 39 years. 2. Two cases of Trade Eczema. Both patients were middle-aged women who worked as "scratch brushers." The irritant appeared to be the "sour beer" with which they brushed the silver goods. 3. Lupus Vulgaris and Lupus Erythematosus in the same patient, a girl, aged 20 years. Lupus began at the side of the nose eight years ago, shortly after she had been nursing a woman who died from consumption. There was some destruction of both alæ nasi and the upper gum was affected. Lupus erythematosus appeared much later and had twice disappeared and recurred. At the present time it had an extensive "butterfly" distribution.—Dr. S. White showed (1) a Post-rectal Dermoid containing Bone; (2) an Unruptured Tubal Gestation; and (3) a Dilated Vermiform Appendix removed from the sac of an Inguinal Hernia.—Dr. S. Riseley showed a case of Double Dislocation of the Lens.—Mr. S. Snell showed a case of (1) Vascular Growth on the Lower and Inner Wall of the Orbit. There was marked proptosis and the surface of the sclerotic below the tumour was covered by a nævoid condition of vessels.—Mr. Pye-Smith read a paper entitled "Four Cases of Gastric Ulcer in which Operation was performed together with One Case not operated on, Two Cases operated on by others, and Three Cases of Exploration for Suspected Perforation."

**GLASGOW SOUTHERN MEDICAL SOCIETY.**—At a meeting of this society held on Oct. 31st Dr. John Stewart gave his Presidential Address. In the course of his remarks he referred briefly to the present position of medical science and dwelt on the necessity of the general medical practitioner keeping himself well abreast of the times. The general practitioner stood between the patient on the one hand and the consulting specialist on the other, and the successful carrying out of the latter's recommendations depended greatly on the general practitioner. The idea, now somewhat prevalent, that the general practitioner must give way in time to the specialist was due, he thought, to the greater elaboration of the art as distinguished from the science. Proceeding, he contrasted the general practitioner of to-day with him of 20 years ago and contended that the practitioner had progressed proportionately with the science and art of medicine. With reference to the objects of the society of which he had the honour to be president he referred in particular to the mutual improvement in professional knowledge accruing to the members and to the corresponding advantages obtained in their work as practitioners. Touching on another

great object of the society—namely, the promotion of amicable relationships between the members—he showed how this friendship could also help the cause of medical science through the rendering of mutual assistance in family practice. In concluding an interesting address he expressed the hope that the future development of medical practice would not tend too much in the direction of a greater subdivision of labour or to an increase of the number of practitioners devoted solely to one particular branch. Rather did he hope for the production of a highly-specialised general practitioner, the very existence of whom would insure that consultants and specialists would be men of outstanding merit in their respective departments.—On the motion of Dr. James Hamilton a very cordial vote of thanks was awarded Dr. Stewart for his address.

**NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.**—A meeting of this society was held at Liverpool on Oct. 18th, Dr. T. B. Grimsdale, the President, being in the chair.—Dr. W. Japp Sinclair (Manchester) exhibited an Improved Portable Apparatus for Continual Irrigation with Fluid at a Constant Temperature and explained its use.—The President showed a specimen of Cancer of the Cervix in a Uterus with three and a half months' pregnancy. The symptoms of bleeding and discharge had first declared themselves with the commencement of the pregnancy. The uterus was removed successfully by vaginal hysterectomy.—Dr. J. E. Gemmell (Liverpool) showed a Uterus with four and a half months' pregnancy and extensive cancer of the cervix, which he had removed by vaginal hysterectomy. Owing to the size of the uterus it had been found necessary, after separating the bladder, to slit up the anterior wall of the cervix and uterus as far as the peritoneal fold and through this opening to empty the cavity. The subsequent steps of the operation were easy and the patient recovered and was reported to be well 12 months later.—The cases were discussed by Dr. Lloyd Roberts, Dr. Briggs, Dr. Garner, and Dr. Davies.—Dr. Lloyd Roberts (Manchester) showed a pair of Large Ovarian Cysts with Papillomatous Degeneration removed by Abdominal Section. None of the cysts had burst and the peritoneum had not become infected by the growths. There was no ascites, its absence being probably associated with the fact of the non-infection of the peritoneum. The patient made a good recovery.—Dr. Sinclair related a case of Cesarean Section performed for the second time in the same patient. The uterine wound was so intimately adherent to the abdominal wound that the new incision was carried directly through into the uterus without opening the peritoneal cavity. The child was delivered through this opening. The patient was not sterilised by ligature of the tubes or otherwise. Both mother and child recovered.—A discussion followed on the dangers of subsequent pregnancy after Cesarean section had been performed, and on the question of sterilising operations under such circumstances. The President, Dr. Lloyd Roberts, Dr. Davies, Dr. Croft, Dr. Briggs, and Dr. Lea took part in it and Dr. Sinclair replied.

**ÆSCULAPIAN SOCIETY.**—A meeting of this society was held on Nov. 1st, the President, Dr. Arthur T. Davies, being in the chair.—The President showed (1) a man, aged 26 years, the subject of marked Myxedema; (2) a specimen of Carcinoma of the Esophagus and Tubercle of the Lung from a man, aged 48 years, who had been losing weight for two years and had had a cough for three years before admission to the hospital; and (3) a Perforation of the Cæcum due to Typhoid Fever in a child, aged four years, whose intestine showed other small ulcers in the neighbourhood.—Mr. Harold Barnard showed a woman, aged 35 years, who had recovered from Strangulated Femoral Hernia. The bowels acted well before the operation. At the operation there was pus in the sac of the small femoral hernia and a little piece of the bowel was gangrenous. The symptoms had lasted for seven days.—Mr. W. Campbell M'Donnell related a case of a man, aged 67 years, who, having an old Scrotal Hernia, collapsed after three days' constipation, and complained of abdominal pain from the hernia to the umbilicus. The hernia was irreducible. On the sixth day of constipation he had stercoraceous vomiting. After nine days' constipation the bowels acted and recovery ensued.—A discussion followed.

**NEWPORT MEDICAL SOCIETY.**—At the annual meeting of the Newport Medical Society held at the Newport and County Hospital, Cardiff-road, the following officers for the session 1901-1902 were elected:—President: Dr. T. G.

Macormack. President-elect: Mr. C. Stuart Vines. Honorary secretary and treasurer: Dr. J. Howard-Jones. Honorary librarian: Mr. A. Falconer Hayden. Committee: Mr. O. W. Morgan, Dr. Garrod Thomas, Mr. H. E. Williams, and Mr. W. Basset.—The honorary secretary reported that the membership had increased during the last session from 27 to 33. At the next meeting, which will be held on Friday, Nov. 29th, Mr. C. Stonham, C.M.G., who was recently in charge of the Langham Field Hospital (Yeomanry Hospital) in the South African War, will read a paper on "The Surgery of the Boer War."

## Reviews and Notices of Books.

*The Case for the Factory Acts.* Edited by Mrs. SIDNEY WEBB, with a Preface by Mrs. HUMPHRY WARD. London: Grant Richards. 1901. Pp. 233. Price 2s. 6d.

THIS book is described in the words of one of its authors as being "the outcome of a small conference of ladies of all shades of opinion, yet agreeing in a common belief in the advantages of factory legislation, and especially in the advantages to working women of such legislation." At the conference it was decided to form a society, which was named the Labour Law Association, and "as a first step the association decided to get a small book written." Mrs. Sidney Webb, Miss Clementina Black, and Miss Tuckwell were appointed to arrange for the preparation and publication of the book, and these ladies have written respectively on the Economics of Factory Legislation, Some Current Objections to Factory Legislation for Women, and the More Obvious Defects in our Factory Code. The other two chapters are entitled, The Historical Development of the Factory Acts, written by Miss B. L. Hutchins, and Colonial Developments in Factory Legislation, by Mrs. W. P. Reeves. There is an appendix of three pages, giving a list of books recommended to those who wish for further information.

Mrs. Sidney Webb, in the first paper, states that women did not concern themselves with such matters as factory legislation a century ago, and that "the women of to-day are no cleverer" than the men of 100 years ago. But the women of to-day have this great advantage. They can study the history of factory legislation and they can see that men began "by making every mistake that could possibly be made on the subject." Unfortunately, some women even now, it seems, are arguing exactly as the men of their class argued when they too had no experience to guide them. A word of caution is required by such people, and Mrs. Webb gives it. "My warning is," she says, "to form no conclusions till you know the facts." It may be presumed that Mrs. Webb considers that she is armed with this knowledge, and it is interesting to see how she applies it to the solution of difficulties which have been the despair of less enlightened people. A true knowledge of the economics of factory legislation leads her to throw a new light on agricultural depression. Some trades are regulated by the legal enforcement of common rules. These trades tend to expand. "The farmer has been free from all common rules. He has always been free to hire his labour at the lowest possible wages." He is able to insist that the day's toil shall endure from sunrise to sunset, and he is not obliged to take expensive precautions to insure his labourers against the effects of unhealthy exposure. "Poor agriculture" has therefore "gone increasingly to the wall and finds itself losing more and more even of the home trade." Is it too much to hope that Mrs. Webb will be able to draw up the regulations which are necessary to put agriculture on a firm footing and at the same time increase the comfort of the labouring classes? At present it is to be feared that shepherds often work more than an eight-hours' day, and

that ploughmen are occasionally exposed to inclement weather. It would be a noble work even for a "brilliant writer, economist, and historian"—all of which qualifications we have Mrs. Humphry Ward's authority for saying are possessed by Mrs. Webb.

Miss Clementina Black in her essay on Some Current Objections to Factory Legislation for Women incidentally informs us that "a publisher does not offer a lower royalty to Mrs. Humphry Ward than to Mr. George Meredith." And this fact may perhaps incline readers to weigh well Mrs. Ward's golden words and to accept her opinion that the writers are "well acquainted with the subjects on which they speak." For her own part she modestly claims "no special knowledge of the great matters with which they deal," but she turns to the "vast English public" with "beckoning finger" which expresses the profit and pleasure she has derived from the book, and she passes on to express her regret that more is not generally known of the Factory Acts, their origin and their results. "What the Factory Acts are—how they came about and what have been their effects. Strange! that of one of the noblest chapters in the history of the nineteenth century there should be so little general knowledge among us to-day." There is plenty of good sound literature on the subject, and to those seriously interested in the matter it may be worth while to point out that what the Factory Acts are may best be understood by reading them attentively, and that copies may be obtained at Messrs. Eyre and Spottiswoode's. The way in which they have been administered is best seen by reading the annual reports of the Chief Inspector of Workshops and Factories. To the imaginative writer, however, facts may have a repressing influence, and if Mrs. Ward had read only the latest of the factory reports it would have prevented her from writing her preface in its present form.

It has been incidentally mentioned that the book contains an appendix to which those wishing to make a study of the subject are recommended. The exact treatises which we have mentioned are not included in this list, but it mentions two books by "S. and B. Webb," one by Sidney Webb and Harold Cox, and two by Mrs. Sidney Webb. In her essay on the More Obvious Defects in our Factory Code Miss Gertrude Tuckwell points out that owing to recent agitations on the subjects of lead and phosphorus poisoning "the public has learnt that there are in certain trades the added danger presented by liability to some special disease." The late Dr. J. T. Arlidge's great work on the Hygiene, Diseases, and Mortality of Occupations was published as long ago as the year 1892. It is not included in Mrs. S. Webb's list of books.

Miss B. L. Hutchins in her essay on the Historical Development of the Factory Acts, instead of following the Acts in chronological order, adopts the classification used in a German text-book on the subject and treats of them under their different aspects: (1) extent of their application to industries and classes of persons; (2) scope and protection, including limitation of hours, provision for health and safety, and education; and (3) method of administration. The essay, though not up to date and occasionally ungrammatical, is not without merit, and the writer has apparently taken pains to get a good general idea of the subject on which she wishes to instruct the public.

Mrs. W. P. Reeves's article on Colonial Developments in Factory Legislation is not entirely lacking in the element of humour. Victoria and New Zealand, we are told, furnish "the most progressive factory legislation." Both colonies have had the courage to adopt principles of labour legislation which other countries "are still painfully boggling over." In one of these enlightened and progressive countries a wide definition given to the term "factory." A wife and her husband still count as one person, but any two persons not married to one another constitute "a factory" when they are working together.

"A mother and child make a factory and have to be registered as such. They must observe factory regulations as to hours and sanitation and are open to inspection at all hours." This thing apparently seems well in the eyes of Mrs. W. P. Reeves, and the system generally, she thinks, has its lessons for the mother country. Possibly it has. Perhaps in this respect the mother country will contrive to "boggle" on as it is.

To the few people who know about the Factory Laws and their administration and who have sufficient leisure for light reading this book may prove amusing, but with the exception of Miss Hutchins's essay on the Historical Development of the Acts (which might with advantage be expanded, brought up to date, carefully edited, and published separately), the book cannot be taken as a serious contribution to the literature of the subject.

*A Text-book on the Practice of Medicine.* By Dr. HERMANN EICHHORST, Professor of Special Pathology and Therapeutics and Director of the Medical Clinic in the University of Zürich. Authorised translation from the German. Edited by AUGUSTUS A. ESHNER, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic and Physician to the Philadelphia Hospital. Vol. I., pp. 628; Vol. II., pp. 590. With 84 Illustrations. London and Philadelphia: W. B. Saunders and Co. 1901. Price 26s.

For purposes of reference this text-book will be found useful, as it abounds in details that are not usually found in English text-books. Students will, however, be rather confused with the numerous sub-divisions under which most of the diseases are arranged. For instance, it would but little benefit a student preparing for his examinations to learn that "several forms of endocarditis have been distinguished and they have been designated ulcerative, verrucose, and contracting." The last term is not used in English manuals, and we doubt whether any student would recognise the phrase "recurrent contracting endocarditis" as designating chronic valvular disease of the heart which has again become acute. The part of the work dealing with Diseases of the Nervous System is well carried out, although here again we are inclined to cavil at the numerous sub-divisions occurring under the headings "peripheral paralysis" and "neuralgia."

For a general text-book of medicine an unusual space is allotted to Diseases of the Skin, but for reference this is not at all to be deplored.

In the parts of the work devoted to treatment the decimal notation is retained as in the original, but the British equivalent is always given. The book is also of interest as a comparison between the Swiss and English methods of considering disease and its treatment, and those who are unable to read German will thank Dr. Eshner for the very able translation which he has made of Dr. Eichhorst's text-book.

*Modern Obstetrics, General and Operative.* By W. A. NEWMAN DORLAND, A.M., M.D. With 201 Illustrations. Second edition, revised and enlarged. London and Philadelphia: W. B. Saunders and Co. 1901. 8vo. Pp. 797. Price 16s.

To this, the second, edition of his text-book Dr. Dorland has added chapters on the Surgical Treatment of Puerperal Sepsis, Infant Mortality, Placental Transmission of Disease, the Serum-Therapy of Puerperal Sepsis, and the Role of the Liver in the Production of Puerperal Eclampsia. He holds that serum-therapy to be effective requires firstly, the accurate recognition of the form of infection with the early employment of the appropriate antitoxin; secondly, the dilution of the poisoned blood by the active introduction into the system of a normal salt solution, either by hypodermoclysis, by rectal clysmata, or by direct intravenous transmission; and thirdly, the restoration of the blood to

normal condition by measures that will increase leucocytosis or that will produce hyper-leucocytosis as from the administration of the nuclein preparations. The plan is still followed in this edition, as in the first, of giving the measurements of the foetal head and the pelvis in inches with their exact equivalents in centimetres to four places of decimals. The student cannot be expected, and will not try, to remember such figures. The easy method of regarding one centimetre as two-fifths of an inch and expressing the fraction as fifths of inches, or half a centimetre, is preferable to the one adopted, and is sufficiently accurate for all the purposes of pelvimetry. In discussing the differential diagnosis of various conditions, such as pregnancy and ovarian tumours, very useful tables are given containing the physical signs and symptoms likely to be of most use in making such a diagnosis. The line of practice advocated differs in a good many instances from that adopted in many English text-books, but Dr. Dorland's treatment is on the whole moderate and sound. In discussing post-partum hæmorrhage he would rely upon gauze plugging of the uterus before trying the effect of a hot douche, an order of procedure which we should reverse. Dickinson's method of controlling the hæmorrhage in such cases by seizing the uterus through the abdominal wall, lifting it out of the pelvis, and compressing it against the spine while the lower hand grasps and manipulates the cervix, is described and recommended. The book is not so good as many of our English text-books, but is on the whole trustworthy and appears to find some favour amongst American students and practitioners.

*Archæology, Education, and Medical and Charitable Institutions of Glasgow.* Edited by MAGNUS MACLEAN. Glasgow: Published by the Local Committee for the meeting of the British Association (James Maclehose and Sons). 1901. Pp. 239. Price 3s. 6d.

IN connexion with the meeting of the British Association for the Advancement of Science which has this year been held in Glasgow the local committee has prepared three volumes, one of which is now before us, the other two dealing respectively with the Fauna, Flora, and Geology of the Clyde Area and the Local Industries of Glasgow. Mr. MacLean deserves credit for the manner in which he has brought within moderate compass and arranged in a convenient form an immense mass of information on a great diversity of subjects. As the title indicates, the book is divided into three sections and consists of 43 separate articles, most of them being by different authors, whose names are given. Part III.—Medical and Charitable Institutions—includes 29 such sub-headings contained in 60 pages, the most important of them having for their subjects the Faculty of Physicians and Surgeons, Anderson's College Medical School, St. Mungo's College Medical School, the Glasgow Royal Infirmary, the Western Infirmary, the Victoria Infirmary, Poor-law Hospitals and Infirmary of the Parish of Glasgow, Asylums of Glasgow, and Municipal Fever Hospitals. The University is described under Part II.—Education.

*Diseases of the Rectum.* By WILLIAM ALLINGHAM, F.R.C.S. Eng., and HERBERT ALLINGHAM, F.R.C.S. Eng. London: Baillière, Tindall, and Cox. Seventh edition. With 69 Illustrations. Pp. 471, demy 8vo. Price 12s. 6d. net.

THIS work is already so well known and its practical nature so valued that a seventh edition does not require elaborate criticism at our hands. The alterations are the work of Mr. Herbert Allingham, and his views on inguinal colotomy particularly, and on the subject of excision of the rectum for cancer, on which questions the chief differences from the original edition arise, are also familiar to medical readers. Mr. H. Allingham considers the question of age in the subjects of cancer of the rectum of the very highest

importance as regards the decision whether or not to employ excision. He finds recurrence in young subjects of most disheartening frequency in spite of the freest removal, and those who are familiar with his operative methods will not be inclined to accuse him of timidity in dealing with cases that require drastic measures. In performing excision he always employs a modification of Kraske's method, except for cases in which the disease is limited to the neighbourhood of the anus and sphincters. In these cases the perineal route is chosen. The practitioner will find the chapter on After-treatment of Cases of Operation for Hæmorrhoids of the greatest assistance. This is a subject that, considering the extreme frequency of the cases and the serious inconveniences arising from lack of careful after-treatment, does not commonly receive enough attention from the general practitioner, or even from the surgeon.

Another point upon which this book may be carefully studied with advantage is the question of palliative or operative treatment in cases of hæmorrhoids. The authors discuss the matter closely, showing what cases may reasonably be treated without any operation and what kinds of milder treatment are most suitable to their cure. The ligature is to be used in a vast proportion of cases. Mr. H. Allingham does not recommend cutting off the hæmorrhoids and is careful to secure a narrow base for application of the ligature. His method necessitates a longer convalescence than do some others, but Mr. Allingham claims for it that it secures practically absolute freedom from recurrence of the affection for the cure of which it was employed. As regards cancer of the rectum Mr. H. Allingham's work on inguinal colotomy has done much to secure for the operation its present favourable position. The operation as he performs it is one of great simplicity and need never be avoided on account of the patient's debility or abdominal distension. The most recent modification in the method is the abolition of the mesenteric stitch in favour of a Spencer Wells clip. This is passed through the mesentery closed and is then made to rest on the abdominal wall, gripping a piece of gauze. Thus the clip cannot slip through from the blade-end and the handles prevent it slipping through from the other. A few stitches are inserted between the skin and the musculo-serous coats of the bowel. The authors give excellent practical directions for finding the bowel when any difficulty arises and say: "There is no excuse for not being able to find the colon, nor is there any for making a mistake as to what part of the intestine is the colon. We have never yet seen a case in which both longitudinal bands and appendices epiploicæ have been absent in the large intestine." We have said enough to show that the seventh edition of this work will confirm the position which it already holds as a thoroughly sound and practical guide to the treatment of diseases of the rectum.

*Diseases of the Nose and Pharynx.* By J. B. BALL, M.D. Lond., Physician for Diseases of the Throat, Nose, and Ear, Lecturer on Diseases of the Nose and Ear, West London Post-Graduate College; formerly Physician to the West London Hospital. Fourth edition, 61 Illustrations. London: Baillière, Tindall, and Cox. 1901. Pp. 439. Price 7s. 6d.

THE last edition of Dr. Ball's book was only published in 1898, which is a proof of its popularity. He has not increased the size of the book since his last edition, though certain small additions and corrections have been made. He has thus been able to keep the work within a moderate compass while giving, as we have said before with regard to previous editions, a concise and intelligible description of the diseases of the nose, naso-pharynx, and accessory cavities. His views on general diagnosis show that Dr. Ball is able to impart his knowledge to others clearly and

concisely, though there is certainly one point in which improvement might be expected. The want of good drawings of pathological states of the nose and nasopharynx, to which we alluded in our earlier reviews of Dr. Ball's book, is still evident.

The chapter on Methods of Treatment contains valuable information of a practical character with regard to syringing and irrigating the nose. While speaking of inhalations again Dr. Ball gives many useful hints, and the same may be said of the directions for the use of the galvano-cautery. We quite agree with Dr. Ball in thinking that the existence of a non-diphtheritic membranous rhinitis cannot at present be denied; in fact, we think he might have made the statement in stronger terms. In the treatment of chronic rhinitis the directions to be given to the patient with regard to sniffing and blowing the nose are well worthy, we think, of a more wide application than is generally given to them; and we endorse Dr. Ball's veto with regard to the use of astringent sprays and powders in this disease. Dr. Ball is not impressed with the theory that ozena is at all frequently a sequel to suppuration in the accessory sinuses, and whether his view that this disease (fœtid atrophic rhinitis) will be proved to be due to a specific micro-organism is sound we venture to doubt. In operations on adenoid vegetations Dr. Ball declares his preference for Gottstein's post-nasal curette, having now entirely given up using any form of forceps. He also prefers the use of chloroform for young children, and ether for older children and adults, and, for his own part, is not in favour of nitrous oxide gas.

The chapter on Reflex Nasal Neurosis is very complete, and in speaking of hay fever Dr. Ball describes every approved variety of treatment. Further points upon which we congratulate Dr. Ball are that when discussing deformities of the septum he has not been led into those subtle and useless subdivisions which have been adopted by some writers; while the parts of the book on morbid growths and infectious disorders of the naso-pharynx and pharynx are excellent; as is the description of pharyngeal diphtheria.

#### LIBRARY TABLE.

*Surgical Applied Anatomy.* By Sir FREDERICK TREVES, K.C.V.O., C.B., F.R.C.S. Eng., consulting surgeon to the London Hospital, &c. New edition, revised by the author with the assistance of ARTHUR KEITH, M.D. Aberd., F.R.C.S. Eng., Lecturer on Anatomy at the London Hospital. Twenty-fourth thousand. London: Cassell and Co. 1901. Pp. 571. Price 9s.—This the last edition of Sir Frederick Treves's admirable manual can only be said to be an improvement upon its predecessors by reason of the most modern views of surgery being incorporated in it, for all the other issues of the book were as complete as they could be, having regard to the state of knowledge at the time at which they were written. That 24,000 copies have been printed shows that the book is appreciated at its true worth, and we can only say that not only practitioners and senior students will find the book eminently useful, but that junior students who are just commencing the apparently unattractive study of anatomy will find by reading it that the dry facts of that science will have a real meaning and will be imbued with interest. We must give a word of praise to the publishers for printing a detailed statement of the various editions and the dates at which they appeared and can only exhort other publishers to do likewise.

*Unprofessional Tales.* By NORMYX. London: T. Fisher Unwin. 1901. Pp. 248. Price 6s.—This book is dedicated to Ouida and we hope that that accomplished lady values the dedication, for of all the drivel which it has been our bad

fortune to read this book takes first place. Some silly books are amusing—this one is dull. We can do no better than quote a few sentences which express our opinion perfectly: "Convince yourselves that I am perfectly calm.<sup>1</sup> ..... I do not profess to know what it means or whether, indeed, it means anything."

*Home Exercises for Spinal Curvature, adapted from Ling's Swedish System of Medical Gymnastics.* By RICHARD TIMBERG, graduate of the Royal Gymnastic Institute of Stockholm. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Pp. 70. Price 2s. net.—This little book is well adapted for those who are anxious to treat either themselves or those under their charge by means of simple gymnastic exercises involving the use of no apparatus other than a broomstick. Lateral curvature is of course the kind of curvature chiefly dealt with, though angular curvatures are just mentioned. Exercises carefully and rationally used are nowadays, in addition to some simple forms of apparatus, the chief method relied upon for the removal of lateral curvatures, and Mr. Timberg's little book will be found valuable as giving a clear account of the necessary exercises. We are glad to see that he insists upon the advisability of the exercises being supervised by some competent person. But there are many cases in which a patient must do the best he can for himself and careful attention to the rules laid down by Mr. Timberg will enable him to get good results. He can check his position either by standing between two mirrors, or in most cases, at any rate, he can get a friend to tell him whether he is standing straight or not.

*Report on the Health and Sanitary Works in Calcutta for the Year 1900-1901.* By J. NIELD COOK, D.P.H., Health Officer. Calcutta: Printed at the Municipal Press. 1901. Pp. 56 (tables included).—According to the census of 1901 Calcutta had a total population of 843,487, being an increase of 181,927, or 23·7 per cent. over the figures of the census of 1891. In his report on the health of the city during the calendar year 1900 Mr. Cook says that the total number of children born, exclusive of still-births, was 10,773, which gives a ratio of 12·7 per 1000 per annum. The total number of deaths was 36,728, which gives a ratio of 43·5 per 1000 per annum. The "five principal diseases" and the total deaths therefrom were as follows: cholera, 2754 deaths; plague, 8354 deaths; dysentery and diarrhoea, 4126 deaths; fever, 7642 deaths; and small-pox, 1010 deaths. Mr. Cook considers that the mortality of Calcutta is progressing in spite of all the work that has been done and the money that has been spent to improve the sanitation of the town. During the last decade three diseases not previously recorded in Calcutta have made their appearance—namely, influenza, cerebro-spinal fever, and bubonic plague. The maximum shade temperature was 103·6° F. in April; the minimum was 50·8° in January.

*Ceylon: Administration Reports. Part IV. Miscellaneous. Medical.* Pp. 67.—The estimated population of the Island of Ceylon on Dec. 31st, 1900, was 3,612,303. During the year 136,051 births were registered and 100,873 deaths, giving a birth-rate of 38·2 per 1000 and a death-rate of 28·3 per 1000 calculated on the estimated population at the middle of the year. Mr. Allan Perry, Principal Civil Medical Officer and Inspector-General of Hospitals, states that the public health of the island was good during the year 1900. There was an absence of widespread outbreaks of malarial fever, but cases of cholera and small-pox were numerous. The number of cases of enteric fever treated in the various hospitals throughout the island was 224, with 77 deaths. No case of plague

<sup>1</sup> Cf. Pet Marjorie:

"But she was more than usual calm,  
She did not give a single dam."

occurred. In a report published in the appendix Dr. T. F. Garvin states that the Boer Camp at Diyatalawa, 157 miles from Colombo, was opened on August 9th, 1900, when the first batch of prisoners of war from South Africa arrived. The number in camp on Dec. 31st was 4256. The number of deaths up to the end of the year was 73 out of a total population of 4396, or 1·6 per cent. Enteric fever first began in the camp on Sept. 24th; the total number of cases to the end of the year was 601, and of those 50 died, being a mortality of 8·3 per cent.

*The Life History of British Serpents.* By GERALD R. LEIGHTON, M.D. Edin. Edinburgh and London: William Blackwood and Sons. 1901. Pp. 383. Price 5s.—The average dweller in these islands has a hazy idea that snakes are in out-of-the-way places and thinks that they all "sting," that they are all poisonous, and that they are slimy. The better informed person is quite conversant with the grass- or ring-snake and with the adder. He knows that the former is harmless, with the exception that it can put forth a heathenish smell, and that the latter can and does inflict a poisonous bite. He also knows that snakes are not slimy. The expert is aware of the existence of a third kind—namely, the smooth snake, *Coronella Austriaca*. Dr. Leighton is an expert and any ordinary person who digests the book before us will have a greater knowledge of snakes than he ever had before. On the vexed question as to whether the female adder receives her young ones into her gullet for safety when danger threatens, Dr. Leighton, as becomes a scientific man, preserves an open mind. There is, at all events, no reason which renders it impossible for a female adder to swallow her young. Plenty of observers have seen such apparent swallowing or have seen the young adders coming forth from the mother's mouth, but apparently no one has as yet captured a female adder with the young in the gullet. At present we can but say that the fact is not proven.

*Advice to Women on the Care of the Health Before, During, and After Confinement.* By FLORENCE STACPOOLE, Diplômée of the London Obstetrical Society and Lecturer to the National Health Society. Third edition. London: Cassell and Co. 1901. Pp. 184. Price 2s.—This little book, which has reached a third edition, contains a good deal of useful information for women concerning pregnancy and child-birth. It is clearly written and the facts which it is important for a mother or a nurse to know are well described. The author, however, has added a number of prescriptions for use in such conditions as indigestion, diarrhoea, neuralgia, and other disorders of pregnancy. These prescriptions, she states in the preface, have been prepared for her by an "experienced doctor." They are entirely out of place in such a work and should never have been inserted. Under no conditions could we recommend a book which contains such prescriptions, encouraging as it does the foolish and dangerous habit of self-prescribing without the advice of a medical man. We must point out to the author that there is no such thing as a "diplômée" of the Obstetrical Society of London and that she has no right to describe herself as such on the title-page.

*Small-pox: its Prevention, Treatment, and History.* London: Florence White. Pp. 82. Price 6d.—This little compilation is well-timed in its appearance. It is obviously intended for popular use and it is an exception to many medical pamphlets so intended by being accurate and not sensational. The writer, we notice, accepts a microbic origin of the disease without question. The case for vaccination is not so strongly put as is justifiable and as we should like to have seen it put. This defect, however, is to a large extent remedied by a concise appendix giving some authoritative opinions in favour of vaccination, mainly from the pamphlet issued by the Council of the British

Medical Association in 1898. Doubtless this book will find a wide general sale at the present time, and in spite of its somewhat awe-striking cover it is the kind of popular medical work which does the least harm in lay hands. Miss Florence White is, we imagine, the first lady-publisher to issue anything of this kind, and she may be congratulated upon her enterprise.

#### JOURNALS AND MAGAZINES.

*The Scientific Roll and Magazine of Systematised Notes.* Conducted by ALEXANDER RAMSAY. Bacteria. Vol. I., No. 3. London: Published for the proprietor by R. L. Sharland. 1901. Pp. 31. Price 1s.—This publication has aims somewhat similar to those which were possessed by the "Annus Medicus." The present number is concerned with bacteriology. The names of the authors are placed alphabetically under the year in which their communications were published. In order, therefore, to find a certain reference the reader must be aware of the name of the author and not only of the nature of the communication. If the reader wishes to ascertain what has been written concerning certain subjects he has to glance through the whole publication to find the information he requires. As it stands, however, the publication should prove a valuable one. We are informed that the number of subscribers is now 45; when this has increased to 200 the work will be issued monthly. We trust the desired number will be forthcoming. We should add that the roll is not drawn from English sources only, but foreign works, especially German and French, have also been consulted.

### New Inventions.

#### THE FUMELINE LAMP.

THE fumeline lamp represented in the accompanying illustration is used for the vaporisation of a volatile antiseptic or disinfectant. It consists of a cylindrical support about three and a half inches high and a shallow dish or saucer, both made of tin-plate. Fumeline is the designation of a power-

fully antiseptic mixture, two teaspoonfuls of which are put into the dish, and an ordinary night-light is then placed underneath as a source of heat. The apparatus is extremely simple and danger from fire seems to be almost impossible; the bottle containing the fumeline is labeled "poison," and this substance must evidently be kept out of reach of children or delirious persons. The lamp is so constructed that if the light is not required in the room

the night-light may be shielded from view. The agents for the apparatus are Messrs. William Edwards and Son, 157, Queen Victoria-street, E.C. The price, including a supply of fumeline, is 2s. 6d.

**WINSLEY SANATORIUM FOR PHTHISIS.**—At the meeting of the Sanitary Committee of the Bath Town Council held on Oct. 28th the sub-committee recommended that the Council should contribute £500 towards the cost of the Winsley Sanatorium and that the corporation should have the right of the use of two beds at an annual cost of £65 each and also be represented on the committee of management of the institution. The Sanitary Committee unanimously supported the recommendation, which will now be brought before the town council.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 9, 1901.

## Dr. Glover and the General Medical Council.

IN another column will be found a letter from Dr. GLOVER announcing his intention not to offer himself as a candidate at the forthcoming election of Direct Representatives of the medical profession upon the General Medical Council. Dr. GLOVER'S reason for his action is one that must be satisfactory to everybody, however much the course that he is taking may be regretted. He is warned by his medical advisers that he cannot, with safety to himself, discharge the onerous duties of practice and at the same time support the grave and delicate responsibilities that devolve upon the tiny group of members who represent upon the General Medical Council the popular vote of the profession as a whole. It is characteristic of Dr. GLOVER that when he found that he could not give his best to the profession he retired rather than offer services which, tried by his own high estimate, he was not able to deem completely efficacious. Dr. GLOVER has served the medical profession as a Direct Representative on the Council for 15 years, having been originally elected in 1886, the year when the principle of direct representation was conceded, with Mr. WHEELHOUSE and Sir WALTER FOSTER as his colleagues. He was re-elected in 1891 at the head of the poll with the same colleagues, and was again re-elected in 1896 with Dr. RENTOUL and Mr. GEORGE BROWN. During the whole of this long service he has had ever before him his desire to render the profession that he loves an honourable and dignified calling.

We do not propose to enumerate the claims that Dr. GLOVER has upon the consideration of his large constituency. Are not his actions at the Council Board recorded in page after page of the reports of the proceedings at the General Medical Council, and do they not always show that his single ambition was to discharge his trust worthily and wisely? But we may remind our readers in a few words that their special confidence in Dr. GLOVER, as shown by electing him and re-electing him as often as he was able to offer himself to their suffrages, was particularly justified. Dr. GLOVER has not been a noisy advocate of his virtues, and in his brief election addresses he never made enormous promises, but his work was sure and sterling. One of his first votes in the Council was against discussions *in camera*, which were then considered more necessary than they are now, and which he stated should be reduced to a minimum. This was a very early declaration that hole-and-corner legislation by a small group for an enormous number of educated men could not be tolerated—it was tantamount to an assertion that the medical profession have a right to demand from the General Medical Council, and not only

from the Direct Representatives but from every member of that Council, an account of their conduct at the deliberations of the Council. The only way in which the medical profession could learn which members of the Council had a proper conception of their duties and which had not was by publicity. We make no secret of the fact that Dr. GLOVER was here carrying on the policy of THE LANCET, for it is perfectly well known that he has been for many years a valued colleague on the staff of this paper; but what we want to bring out is the credit that is due to Dr. GLOVER for the present familiarity of the medical profession and the lay public with the transactions of the General Medical Council. Dr. GLOVER, again, was particularly zealous in his efforts to elevate the standard of medical education of the country, while it was upon his motion that the Council instructed its Executive Committee to report on the disciplinary functions of the examining bodies, both universities and corporations. Here he showed himself the true reformer, raising a voice against the pernicious view that the General Medical Council is a congeries of gentlemen representing the interests of some two dozen educational centres instead of a body instituted for the protection of the public and employed in safeguarding the health of the public by educating the medical profession up to a proper pitch and ensuring that they regulate their conduct according to a high ethical model. The Acts of Parliament under which the Council exists provide but one punishment for all offences, whatever their degree and whatever their kind, so that the ignorant and half-accidental delinquents find themselves treated with the same rigour as the convicted forger—that is to say, their names are removed from the Medical Register if their "infamous conduct in a professional respect" is proved. Dr. GLOVER perceived that enormous pressure could be brought to bear upon the weak vessels of the medical profession through the examining bodies whence they obtain their qualifications to practise, what was required being that the examining bodies should consent to play their part. Hence his motion that a report should be prepared which would show what powers, if any, the various examining bodies possessed over their graduates or diplomates, for when such returns were made it would be certain that no university or corporation would dare to lag behind its fellows for long. All would have to show themselves anxious in the same degree to keep the Medical Register pure. The motion was a direct attack upon the narrow spirit which would make the representative of an examining body upon the General Medical Council conceive it to be his one duty to save his own corporation trouble, and it has already borne excellent fruit.

With regard to the question of registration of midwives Dr. GLOVER spoke with no uncertain voice. He agreed—and it is difficult to see where dissentients can be found—that something must be done to protect the lives of the parturient poor from the risks of being attended by women entirely ignorant of the first elements of puerperal safety. He considered that the training needed for midwives should be of a character to enable them to act as midwifery nurses in safe cases, while they should be required in all others to send for a medical man. He entirely

disapproved of the proposal of a course of three years' training for midwives to be followed by examination and registration:—firstly, because such a measure would create a class of nurses too costly to serve the needs of the poor women who constitute the section of the population requiring assistance during childbed; and, secondly, because there would be a danger under such a scheme of creating a semi-medical order, who would be competitors with medical men for patients, while not possessing the necessary qualifications. Certain shades of Dr. GLOVER'S views on this question, and on others, did not meet with our approval, a fact which did not turn him from his independence or shake our confidence in the valuable nature of his services to the medical profession as Direct Representative upon the General Medical Council. At about the date when we expected to be advocating the claims of Dr. GLOVER to a fourth election upon the General Medical Council we find ourselves bidding him adieu in his character of a Direct Representative. We do so most regretfully, and we know that our sentiments are very generally shared.

### The Report of the Committee on Navy Rations.

THE Committee appointed to inquire into the question of navy rations, meal hours of the sailors, and the management of canteens had a very important and at the same time very difficult subject submitted for their consideration. Not only had they to take up the general question of the victualling of the fleet in being, with special reference to the sufficiency or otherwise of the present ration and to the hours for meals on board ship (and consequently to the arrangements for the issue of the ration), but the retention of the system of "savings" which has been in force for upwards of 100 years, and to which the men of the navy are much attached, had to be taken into account, as well as the influence of the extension of late years of the system of canteens on shipboard. The effect which any of their recommendations might have, moreover, on the victualling of the fleet in time of war had to be borne in mind. By "savings" is meant monetary payment in lieu of rations and articles of diet in kind. Where the conditions are so complex and so many circumstances have to be taken into account, as in the present case, it follows that the report must be largely technical in character. It must be studied from an expert point of view, and carefully studied, in order to be properly appreciated and understood. We publish in another column a review of the report from the unconventional pen of a correspondent who is in an admirable position for knowing what he is talking about. It will be seen that he is very critical, but it will also be seen that he comes to the conclusion that the recommendations of the Committee are praiseworthy. We think that any of our readers who study the report will find themselves in agreement with him.

It is clear that the Committee have expended a great deal of time and labour in taking and digesting the evidence of a large number of witnesses able to give practical information. We do not suppose that there is, or can be, any finality about the recommendations of the Committee in a matter of dietary where so much may be learned from actual trial and experience, but if we may judge from our examination of

them and from the opinion expressed by some experienced naval medical officers to us, we may safely congratulate those responsible for the report on having taken a decidedly forward step in advancing the health and comfort of our sailors. The constitution of the Committee was on the whole a good one, the great predominance of laymen proving not so objectionable as might have been expected. But where so complicated a subject as the nutritive value of aliments and food-stuffs in relation to health and work is concerned it would have been strengthened by the presence at the council board of some scientific expert accustomed to laboratory investigations to help Deputy Inspector-General IRVINE, the one medical member of the Committee. The medical evidence, if somewhat conflicting as to the sufficiency or otherwise and the dietetic qualities of the ration, was practically unanimous in regard to its lack of variety. In Table 3 of Appendix IV. of the report the nutritive values of naval and other dietaries in respect of albuminous matters, hydrocarbons, and carbohydrates are set forth; those of the standard diet for a man undergoing laborious work, for an English railway navvy, an Australian stockman, and a prize-fighter in training are also given by way of contrast and comparison. In this way it is possible to gauge at once the reason and force of the recommendations of the Committee; and this clearness is a feature of blue-books and departmental reports the absence of which we have more than occasionally to regret.

There is some reluctance occasionally on the part of those concerned to enforce strictly their powers in dealing with contractors. We are glad to notice that the Committee lay much stress on the point that quality alone, and not price, should be the consideration which should decide the acceptance or rejection of all articles supplied for the consumption of seamen. The Committee had to deal with a very important question in imposing a limit on the quantity of fresh meat which might be "saved" while ensuring that the consumption of fresh meat should be sufficient to keep the men in good health. "The proportion of the fresh meat ration which," the Committee recommend, "may be saved should be limited to one-third at the home ports, as in the Channel squadron, and on foreign stations." It is also suggested that fresh mutton instead of fresh beef should be issued as a change when desired. While some reductions in the present ration are recommended a number of additions are proposed by the Committee which will have the effect of making it a more varied and desirable dietary. Pages 39 to 42 of the Report are taken up with a complete summary of the recommendations of the Committee on the subjects referred to them for consideration, and may be read by those who have not leisure to read the whole Report. But the interesting subject of the victualling of our fleet is treated by the Committee in so readable a fashion that we believe most medical men will not be content with the summary.

### A Material Age.

FOR all who love ceremony this is a sad age. The hurry of modern life leaves no time for all those stately courtesies and dignified rituals that adorned the "spacious days" of our forefathers. In our own profession at this time of the year the decay of all such decorative proceedings is

particularly impressed upon our minds by the fading custom of introductory addresses at the medical schools. Even these ceremonials, of no great antiquity and originally of obvious worth and purport, are gradually being condemned as too ponderous for the spirit of the age. The student, though only at the beginning of his career, must not be asked to sit still for an hour while a wise man discourses in a general fashion upon the profession in which he is distinguished and in which his hearers hope to become so. Introductory addresses are being pushed out of the lecture theatre of the medical schools as classics are out of the class-rooms of the public schools. As a result of the wide competition and the ever-growing accumulations of knowledge in every profession—nay, in every branch of every profession—there is no time or place to-day for the superfluous. We are all perforce utilitarians and can only spare attention for that which directly furthers our particular aims.

At a recent famous trial for bigamy nobody paused to admire the historic house, the quaint ceremony, or the splendid apparel associated with the proceedings; but everybody was busy deploring the time that these old usages demanded and the expense involved in what might have been a much quicker and cheaper administration of justice. Time and money, how to save the one and to make the other,—these are the ruling questions of modern life. The average man is in a fair way to forget that there are other things worth considering; and only the very wise or the very wealthy care to be lavish of time and to forfeit money in the pursuit of learning, peaceful and unremunerative, undertaken simply for its own sake and the sake of sound knowledge to be acquired. Nowadays everything must move fast and must have a direct purpose. The altered manner is apparent in all the affairs of life. Starting with one old custom which used to mark what is often the first important epoch in a man's life—the wedding-breakfast—we can see a general disappearance of all grave and stately, if perhaps tedious, formalities. Weddings to-day are unaccompanied by breakfasts. It is more to the point to encourage some proceeding by which more friends can be accommodated at a less cost of time and of money. To consider the relative comfort of your guests is no part of the modern programme, so a couple of hundred guests and relatives are crowded for a few hot, jostling, champagne-sipping moments into a room where a quarter as many of their grandparents would have solidly enjoyed themselves for a couple of hours. Conversation as a formal proceeding we have long dispensed with, and the rapid inanities of the fleeting "at home" replace the solemn speeches, the weighty toasts, and the cheerful dialogue of the wedding-breakfast.

There is no department of affairs perhaps in which this general change of manner is more apparent than in the personal conduct of medical matters. The very idea of a "doctor" in earlier days conjured up the notions of deliberation, gravity, and a solemn and formal procedure. To-day we picture him rather as a brisk man, of keen eye and few words. We have no hesitation in declaring our practical modern methods to be as much to the patient's advantage as they are to that of the medical man, but the contrast is none the less marked. Then, he would begin

his visit by formal, possibly learned, conversation, and terminate it with rounded periods of hope or grave expressions of anxiety confided to the relatives; now he sees his patient on his arrival, has a few words with the nurse, and jumps on to a bicycle. He is summoned by a telegram, prescribes through the telephone, and arrives in a motor-car. The old-fashioned medical man was in nothing more precise than in the fashion of his dress. To have visited a patient in anything but his most formal costume would have shocked his own sense of propriety and would have given the patient serious misgivings as to the correct professional standing of his medical attendant. It is a part of the general change of manners that gives medical men to-day a far wider freedom in this matter. The world takes nowadays a more liberal-minded view of these minor questions. The practical convenience necessitated by modern conditions prescribes behaviour. At a time when ladies ride bicycles and smoke cigarettes and when a Royal Princess has satisfied her curiosity and spirit of adventure by travelling outside an omnibus, who will ask the medical man to restrict himself to the frock-coat of rigorous professional propriety? Opinion is more sensible and untrammelled than it used to be, and it is recognised that a man may be an active surgeon or a careful physician even if his coat has no tails to it. In the country, perhaps, professional costume was always more or less adapted to climate and to locomotion. The country doctor did not ride in the faultless attire of his town brother or drive in such "correct" apparel as the latter habitually wore. Now, however, the considerations of practical convenience are allowed full play in towns too, and, as the season demands, the short-coated suit and the straw hat are not altogether taboo. It is right, however, that a medical man should always be careful and quiet in the manner of his dress. He must not allow flashiness to play a part in his costume, and our younger readers will do well to remember that though a freedom is theirs now which was denied to their fathers, still it behoves them to see that they dress strictly as gentlemen should. Better the inconvenient staid limitations of a black frock coat than that a suit only fitted for the racecourse should be worn at the bedside. Even in such comparatively small matters as dress wider opportunities entail proportional responsibility, and the young practitioner of to-day must not forget that POLONIUS's advice in the matter of costume is as worthy to be followed now as it has been for the last 300 years.

## Annotations.

"Ne quid nimis."

### THE LONDON SCHOOL BOARD AND ITS MEDICAL OFFICER.

It is a well-known fact in psychology that crowds will, as crowds, do actions which no one of the individual members who compose them would think of doing. In the same manner the London School Board in its corporate capacity acts in a manner in which we do not for one moment believe any one of the individual members would act. The Board's latest piece of work is to dismiss its medical officer in a peculiarly ungracious way. We take the following facts

from an article which appears in the current number of the *Journal of State Medicine*, the editor having courteously favoured us with an advance proof. This journal is the official organ of the Royal Institute of Public Health, of which body Dr. Smith is also the President, so we may take it that the statements contained therein are authenticated and they are borne out by quotations from the minutes of the meetings of the School Board. The facts are these. In 1890 Dr. Smith was appointed as medical officer on probation to the Board on the understanding that he was to be debarred from private practice and that he was not to be allowed to hold any appointment which interfered with the proper performance of his duty to the Board. In May, 1890, two months after the appointment, Dr. Smith wrote to the Board intimating that if he was required to give "his whole time" in a rigid sense to the Board his position would be untenable. On this letter the Board took no adverse action. In fact, on May 15th, 1890, the Board decided that Dr. Smith might continue to hold two offices outside the School Board—namely those of medical officer of health of Woolwich and the professorship of State medicine at King's College. In 1899 the General Purposes Committee of the School Board offered to increase Dr. Smith's salary from £600 to £800 per annum on condition that he gave up the medical officership of health of Woolwich. In view of the impending changes to be brought about by the Act for the local government of London this proposal was suspended, and eventually the School Board offered a salary of £800 per annum on condition that all appointments were given up except the King's College professorship. Dr. Smith declined to accept this offer and the School Board then passed the following resolution:—

“That the resolution increasing the salary of the medical officer from £600 to £800 be rescinded; that Dr. Smith be called upon to resign all his paid professional appointments, with the exception of his lectureship on medical jurisprudence in King's College; and that, failing his consent to these conditions, six months' notice be given to Dr. Smith for the termination of his appointment.”

This resolution was passed by the Board on July 25th, 1901. We consider that the School Board has acted in an unfair manner. To begin with it never should have allowed Dr. Smith to hold the appointment of medical officer to itself and other appointments too, especially such an arduous one as that of medical officer of health of Woolwich. It is absolutely impossible for any man to hold satisfactorily two such appointments as that of medical officer of health of a district which had in 1899 a population of 107,324 and that of medical officer to a body responsible for about 500,000 children. In addition to his medical officership of health Dr. Smith was public analyst, and in addition to his professorship he is director of the King's College laboratories of State medicine. But the Board having winked at what must have been a dereliction of duties had no right to go back on itself. The medical officer to the London School Board should be a competent man, he should have a salary of £1000 per annum, he should be required to give his whole time to the duties of his post, and he should be responsible for signing certificates for non-attendance. He ought to keep an eye on the sanitary condition of the schools, the condition of the children, and the health of the teachers. It should also be impossible for him to be able to be dismissed by a body the composition of which changes every few years and the members of which are popularly elected. The persons in whose hands his dismissal should rest are the members of the Education Department. We do not for one moment consider that Dr. Smith should have been allowed to hold such a number of posts that he could not possibly carry out the duties entailed thereby, neither do we think it fitting that panegyrics upon himself as a public servant should

appear in the journal of the Committee of which he is a member—e.g., “We venture to assure Dr. Smith of our sympathy with him and our respect for the dignified position he has taken”—but none the less the Board has acted in a mean, reprehensible manner.

#### DEATH OF A CENTENARIAN.

MRS. ELIZABETH HANBURY, of Richmond, Surrey, died on Oct. 31st, aged 108 years and four months. She was the youngest child of Mr. John Sanderson, who had a warehouse in St. Mary Axe, and she was born in Castle-street, in the parish of St. Alphege, London-wall, on June 9th, 1793. In 1826 she married Mr. Cornelius Hanbury and thenceforth lived for a long time at Stoke Newington in North London. Mrs. Hanbury was a member of the Society of Friends, spoke at the meetings, and was an acknowledged minister. Among the numerous philanthropic and charitable movements which occupied much of her time and energy the visiting of prisoners in Newgate (in conjunction with Mrs. Fry), the visiting of convict-ships, especially those for females, and the work of the Anti-Slavery Society held the foremost place. She was able to read and to write even when over 100 and to go from one room to another of her house when over 107. Mrs. Hanbury has left a son, Mr. Cornelius Hanbury, chairman of the firm of Allen and Hanburys, Limited, an old-established City firm of pharmaceutical chemists. A notice of Mrs. Hanbury, together with a portrait taken on her hundredth birthday, are contained in a recently published autobiography of her daughter, the late Charlotte Hanbury, edited by Mrs. Reid. The funeral took place on Nov. 5th in the Friends' burial ground at Wellington, Somerset.

#### THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

THERE is no need here to remind our readers of how much this Fund has done and is doing for the sick poor of London; but, as in every other organisation for helping others, money is required. It was the hope of the Royal Founder of the Fund—now His Majesty the King—that the resources of the London hospitals should be increased by £100,000 a year. Although this hope has not been realised, yet it is hoped that £50,000 a year has been found, and thus another £50,000 a year remains to be gathered in by some means. The organising committee of the fund, through their chairman, Viscount Duncannon, have suggested that the freeing of the hospitals from debt would be a most acceptable coronation gift to the King and have issued an appeal to this effect. The appeal is being sent to the press, to factories, and to offices. We have every satisfaction in endorsing the appeal, for the London hospitals are kept going by purely voluntary gifts whether in land or in money, while the senior members of the staff either give their services for nothing or else for a few pounds per annum which are paid to them more for administrative reasons than for any other. Of our two oldest hospitals that of St. Bartholomew was founded by an ordinary citizen attached to the Court and afterwards was supported and served by the Augustinian Brothers of the Priory of St. Bartholomew, while St. Thomas's Hospital arose from the Priory of St. Mary Overy, served by brothers of the same order. Guy's Hospital was originally the creation of one man, and thus our endowed hospitals owe nothing to the State or to municipal rates for their funds. Our hospital system is the people's own; it is kept up by private donations and subscriptions; it reflects both the high regard the country has for the sacredness of human life and the sympathy the people feel for its care. In such a city as this, where life teems in restricted areas and throbs in complicated activities, dangers are always threatening the healthy,

and the terrible wear and tear, the stress and turmoil of competition, make deep inroads on the public health. It must be counted to the city's good that the awful fact of suffering is *voluntarily* met by the best surgical and medical knowledge and by nursing accommodation which men, women, and children may promptly claim. To those who take their corporate responsibility seriously these are grateful facts. £50,000 a year: it is at once a large and a small sum. It is about the income of the weekly cost of the war and about one-fortieth part of the sum compulsorily paid in rates to the School Board. But it is not much for London to find, and yet should London be asked to find it all? A great proportion of the patients at a London hospital come from the country; many of them are genuine cases of illness and some are not. We remember one patient who made fortnightly trips to a London hospital from Peterborough for a pint of cod-liver oil. But a London hospital is really a national institution and we think that the appeal might be made to a wider area than that of the metropolis alone. To intending donors we would point out that the fund is admirably administered and that a very small portion of the money subscribed goes in expenses or salaries.

#### THE PRESERVATION OF DEAD BODIES BY FORMIC ALDEHYDE.

THE preservation of dead bodies by some method which will not affect the colour or the pliability of the tissues is a thing much to be desired in the interests both of teachers and students of anatomy as well as of forensic medicine. Such a method has, we think, been found in the vapour of formic aldehyde, and an ingenious apparatus for its application has been devised by Dr. G. de Rechter, a member of the Sanitary Board of the city of Brussels, and his brother, M. F. de Rechter, who is an engineer. The apparatus, which we have had the pleasure of inspecting at the Examination Hall on the Thames Embankment, consists of two compartments, one the disinfecting chamber, and the other which is divided into two for the production of formic aldehyde vapour in the one and of ammonia vapour in the other. The use of this last is to neutralise the formic aldehyde if required. Above each one of the compartments, which are really containers for evaporation over a large surface, is fixed on the outside a sprinkling-receiver containing liquid corresponding for the one part with formalin and for the other with ammonia. These sprinkling-receivers are made in imitation of ordinary oiling apparatus with a visible drop such as those employed in the lubrication of engines. They are airtight and are provided with an air-tube plunging into the liquid in such a manner as to work at a constant level, and, by means of a screw, the requisite number of drops to be given out per hour can be regulated. From the receiver the sterilising or neutralising liquid falls into a collector, which distributes the liquid uniformly on a number of wicks of plaited cotton, hung vertically so as to spread the substance over the largest possible surface, and with a view of ensuring complete draining. In order to produce the circulation of the air throughout the whole apparatus and to ensure progressive saturation in the sterilising chamber a small electric fan should be placed in the passage conveying the vapours. It goes without saying that during the period of disinfection the air circulates exclusively in the disinfecting and formic aldehyde chambers. The ammonia is only used on the withdrawal of the body or other matter which is being treated. On Nov. 4th we "assisted" in the French sense at a post-mortem examination on the body of a man which had been in the chamber since Oct. 12th. The body had not been touched in any way before being placed in the chamber. The limbs and skin were soft and

pliable except on the face, scalp, and the fingers and toes, where the skin was leathery. The brain was somewhat soft but had no disagreeable smell. The intestines, however, and the abdominal muscles showed slight signs of putrefaction, although the smell was slight; the liver, though soft, was of a perfectly normal colour. It must be remembered, however, that this body had been treated by one unaccustomed to the apparatus and had not been kept at a temperature of 12° C. for the first week or so as recommended by MM. de Rechter. The process will be found, we should say, to be of great value both for anatomical and medico-legal purposes, and with regard to the latter point we may mention that experiments have been made with the bodies of animals which had been poisoned by morphine, atropine, strychnine, and arsenic. In no one of these did the formalin in any way prevent the detection of the poisons, but we think that it would be of interest to try an experiment on an animal poisoned with cyanide of potassium or phosphorus. One other use of the apparatus would be in keeping condemned meat for a magistrate's inspection. If put into the apparatus on seizure the meat would undergo no further change. We may add that the agents for the apparatus in Great Britain are Messrs. Thomas Christy and Co., 4, Old Swan-lane, London, E.C.

#### THE REMOVAL OF PATIENTS SUFFERING FROM ENTERIC FEVER.

AT the Kettering Police-court on Oct. 16th Mr. William Mackenzie, the medical officer of health of Raunds, was summoned for a breach of the Public Health Act by aiding and abetting one Frederick Allen unlawfully to expose himself whilst suffering from enteric fever at Kettering. The evidence given was rather conflicting in some respects. It appeared that Mr. Mackenzie was called in to see a man named Allen—one of his club patients. When Mr. Mackenzie arrived at the house he found Allen up and dressed, but as his temperature was 100·2° F. and his symptoms suggested enteric fever, and as there had been several cases in the neighbourhood, he came to the conclusion that the patient was suffering from that disease. Mr. Mackenzie asked if there was a hospital for infectious diseases in the neighbourhood and was assured that the patient would be admitted; he consequently said that if the patient could be taken into the hospital "it would be a good thing." It was in this respect that the evidence varied, the witnesses for the prosecution stating that Mr. Mackenzie advised the patient to go, Mr. Mackenzie himself stating that he merely suggested such a course and said that if the patient did go it was to be "on his own responsibility." Allen consequently went in a cab to the hospital but was refused admission as he did not belong to the district. The prosecution maintained that Mr. Mackenzie ought to have made further inquiries before giving his consent to the patient's removal and that by using a cab Allen had made himself a source of public danger. When Allen returned home Mr. Pretty saw him and five days afterwards he was removed to the hospital. For some reason Mr. Pretty was not called as a witness. We consider that he should have been, for whether the removal of a patient in a cab was a source of public danger largely depended upon the stage of the disease. From Mr. Mackenzie's evidence the patient was apparently in the very early days of enteric fever, probably not later than the third, and as it has been shown that the pathogenic bacilli do not appear in the stools until the ninth day, and as infection by the breath is of the very rarest occurrence, we cannot consider that there was any danger of infection to the public by Allen's removal in the cab, but Mr. Mackenzie took the further precaution of

having the cab disinfected and could not therefore, according to the evidence given, be said to be guilty of the charge for which he was summoned. After consideration the bench dismissed the case against Allen, but considered that "Dr Mackenzie acted very injudiciously in sending the man to Kettering without first communicating with the medical officer there." But on the evidence they did not feel justified in convicting. We think this is rather hard on Mr. Mackenzie. He was certainly acquitted of the breach of the Public Health Act, and the evidence with regard to the reasons why the man went to the hospital for infectious diseases was, as we have already said, most conflicting.

#### THE LAY TREATMENT OF ALCOHOLISM.

A CORRESPONDENT has sent us a little four-page leaflet, dated from "The Lodge, Carnoustie, N.B." We learn from this that "Mr. and Mrs. William Mathie who have had large experience in the treatment of alcoholism have opened the above home, where special attention will be given to those suffering from such a condition. .... The duration of treatment is three weeks, not less, and no restriction as to stimulants is put upon the patient on entering, for as the medicine takes effect the desire for stimulants progressively lessens. The medicine acts directly on the nervous system. ...." An extract from the *Dundee Evening Telegraph* of May 27th, 1901, is given by which we learn that "it is indeed worthy of note that some medical experts have recommended the sending of anæmic young women to the matron for treatment similar to that meted out to other visitors." This statement may mean a great deal more than meets the eye, and we do not believe that any medical expert would send a simple case of anæmia to be treated by a secret remedy. We must confess that we should like to know more about Mr. and Mrs. Mathie and their manager, Mr. Donald F. Cameron.

#### THE PHYSIOLOGICAL EFFECTS OF COCAINISATION OF THE SPINAL CORD.

Professor A. Pitres and Dr. Jean Abadie of Bordeaux have published in the *Archives de Neurologie* for October a valuable paper based on an extensive series of experiments and observations made by them to determine the physiological and clinical effects of cocaineisation of the spinal cord by the method of lumbar puncture. 50 cases were thus studied, the cocaine injection used being a 2 per cent. sterile solution. The following are the chief conclusions reached : 1. The analgesia which follows spinal cocaineisation is due to the action of the cocaine not on the spinal cord, but on its posterior roots the conductivity of which is diminished. The analgesic action is, however, somewhat irregular, hence sometimes the anaesthesia begins in the perineo-scrotal region, sometimes in the thighs or feet—i.e., in detached patches which gradually extend and coalesce. The same fact has been observed by M. Tuffier and M. Hallion. 2. The analgesia is thus progressive and after the operation the restoration of sensibility to pain is similarly not uniform. 3. Cutaneous sensibility to pain (pinching or pricking) is the first to disappear, and later the sensibility to heat or cold. Touch may be erroneously localised at this stage (allocheiria). The sense of contact and pressure on the skin is the last to disappear. 4. The touch of clothing, the hand, or metal on the legs or body may be perceived for a long time, and ether falling on the skin and evaporating gives rise to a sensation of warmth, whereas chloroform similarly applied to the skin gives rise to no sensation. 5. Tickling of the soles of the feet is long perceived by the subject but the usual reflex is not provoked. 6. Cutaneous sensibility to touch is the first to reappear, next the sensibility to pressure, next the thermal

sense, and lastly, the sensibility to tickling and to pain. 7. In four patients the electric sensibility of the skin (noted before the experiment) was abolished after the injection. 8. Deep sensibility of the muscles, bones, and joints is abolished in proportion to the degree of cutaneous analgesia, and when the latter is complete so is the former. 9. Consciousness of position of the limb is generally preserved during the analgesia, the only exception in the 50 cases being a patient who was tabetic. 10. Deep visceral sensibility (testicular and peritoneal) is never totally abolished, though it may be considerably diminished. 11. The knee-jerks and the tendo Achillis reflexes are always modified by the lumbar injection. In normal subjects they are at first exaggerated and then diminished until the normal degree of reaction is re-attained. 12. Sphincter troubles in the form of paralysis of the bladder or rectum are never produced with the moderate doses of cocaine employed. In a considerable minority of cases erections of the penis were noticed to occur. 13. Vaso-constriction occurs in the analgesic areas and the skin becomes pale and comparatively bloodless, scarcely bleeding when pricked. 14. The skin of the lower limbs and lower part of the trunk remains cold and dry, while the face, upper limbs, and upper part of the body sweat freely after the injection. Professor Pitres and Dr. Abadie further state that after simple lumbar puncture they had never observed epileptoid tremblings, contractures, or fibrillary tremors of the muscles, and that nausea and vomiting were rare sequelæ, but that headache was common and was probably due to the toxic effect of the cocaine.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Oct. 30th states that for the week ending Oct. 26th the cases of plague in the Cape Peninsula numbered 2, both Europeans. The cases at Port Elizabeth numbered 4—namely, 1 Malay and 3 natives. For all other places the cases numbered 0. The deaths from plague were as follows: Cape Peninsula, 1, a European; Port Elizabeth, 1, a European; all other places, 0. The area of infection remains unchanged. The cases of plague among persons under naval and military control numbered 2—namely, a private of the 3rd Lancaster Regiment, Greenpoint Camp, and a private of the 3rd Battalion of the Buffs, Simonstown. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Nov. 4th states that for the week ending Oct. 31st there were 77 cases of plague and 47 deaths.

#### THE EAST SUSSEX MEDICO-CHIRURGICAL SOCIETY.

THIS society celebrated the jubilee of its existence by a dinner held on Oct. 31st at the Eversfield Hotel, St. Leonards-on-Sea. The President (Dr. J. W. Batterham) took the chair and a large number of members and guests were present. Among the latter were the President of the Royal College of Surgeons of England (Mr. H. G. Howse), Mr. W. Allingham, Mr. Howard Marsh, Mr. Edmund Owen, Colonel Brookfield (M.P. for the Rye Division of Sussex), the Mayor of Hastings, and Canon H. B. Foyster. After the usual loyal and patriotic toasts Mr. Howse gave the toast of "The Society and its President." He drew attention to the fact that their society was one of the oldest medical societies in the kingdom and complimented them upon the excellence of their rules and regulations, more especially with regard to those which dealt with ethical relations. Dr. Batterham, in reply, said that their society was founded by Dr. Greenhill and a few others in 1851. There were at first 11 members, now there were 50. Their original library consisted of 57 books, now they had one of between 2000 and

3000 volumes. They had tried, and he thought that he might claim with success, to keep themselves abreast of the ever-increasing flood of medical knowledge. As to the success of their efforts in regard to professional good fellowship he had only to point to the understanding existing between the various medical men in the town. Dr. B. H. Allen proposed "Kindred Societies" to which Mr. Edmund Owen responded, and the last toast was that of "The Secretary" proposed by the President and acknowledged in suitable terms by Mr. L. E. Jowers. The society has done good work not merely in a purely professional sense but in the more public manner of taking interest in, and advising the municipality upon, questions of sanitation and hygiene. Therefore, we congratulate it upon its past record and cordially wish for it many more years of useful life.

#### SMALL-POX IN LONDON.

THE returns of small-pox up to Wednesday in this week are better than during last week. On Sunday, Nov. 3rd, there were seven fresh cases admitted to the hospitals of the Metropolitan Asylums Board; on Monday, Nov. 4th, there were 15 fresh cases; on Tuesday, Nov. 5th, there were 12 fresh cases; and on Wednesday, Nov. 6th, there were 4 fresh cases.

#### THE PROTECTION OF NURSE-CHILDREN.

IT is highly satisfactory to know that it is intended to bring under the consideration of Parliament next session a Bill for the better protection of nurse-children. The present Act certainly stands in need of amendment and more especially in respect of the very clauses by which it was made to amend an originally stronger measure. It is generally known that the provisions of the Act for registration and supervision apply only to cases in which more than one child is boarded out and, moreover, to cases in which a sum of less than £20 is paid for each child. For what purpose these conditions were introduced we do not profess to understand. Their practical effect has been to impair in no small degree and for no obvious reason the usefulness of the Act. They serve as gaps in the net through which offenders may freely escape, if only they are sufficiently cunning. The payment of a less or greater sum of money can clearly provide no guarantee for proper treatment if the child should come to be committed to the hands of unscrupulous persons. Neither should the fact of a greater payment entitle the parent or guardian of such a child to dispense with the necessity for registration. This, after all, is the only legal safeguard provided to cover transactions of the kind. Why should the child born in a better condition of life be denied this privilege? Why should exemption be sought for it? There can be no sufficient reason nor can we see any justification for such a course. On the contrary, we recognise an obvious loophole for the evasion of that purpose of justice for which the Act was framed if there is present a desire to evade it. In a recent case of baby-farming at Balham which was investigated under a charge of neglect two infant children were found to have been shamefully neglected and starved, death resulting in the case of the younger. A sum of £40 had been paid down for one of these children and £30 for the other. Obviously the payment of money afforded here no security for the most elementary practice of humanity. No less does the existing law require modification in the interest of single nurse-children. Except for the necessity of obtaining a certificate in the event of death and a medical man to give it such a child is practically without resource unless it be found perchance in a nurse with a conscience. Experience has abundantly proved that such resource has to be well sought for among the women who "nurse" these poor children. We have all along urged the necessity for

registration even in the case of a single child and we would respectfully but most strongly urge upon the Government the necessity of treating the whole subject in a thorough and decisive manner. We feel convinced that no Bill can be expected to secure the proper treatment of such nurse-children which does not provide fully and without reservation for their registration and supervision.

#### TEMPERANCE ADVOCACY IN GERMANY.

THE annual conference of the German "Society for Combating the Abuse of Spirituous Liquors" was opened with a meeting in the great hall of the University of Breslau on Oct. 30th. Baron von Diergardt said that Germany suffered heavily from the incubus of alcohol. Three milliards of marks (£150,000,000) were spent annually in Germany on intoxicants, as compared with 12 milliards spent on food. On an average every member of the population—men, women, and children—consumed in a year 10 litres (2·2 gallons) of pure alcohol, an amount equivalent to 30 litres (6·6 gallons) of spirits. One principal difficulty with which temperance reformers had to contend was the fact that they everywhere encountered persons who were interested in the sale of alcohol. The State itself had a financial interest in this traffic, collecting as it did a revenue of 165,000,000 marks (£8,250,000) from spirits and 100,000,000 marks (£5,000,000) from beer. One-third of the German exports to Togoland and one-seventh of the German exports to East Africa consisted of alcohol. An appeal signed by 42 of the Breslau University professors and teachers has been addressed to the students reminding them of the dangers of over-indulgence in intoxicants and urging them to make a stand against the drinking customs which prevail in universities, especially against competitive feats in beer-drinking and the custom of "Frühschoppen," or morning libations of the same beverage.

#### PRIMARY TUBERCULOSIS OF THE SPLEEN.

IN the *American Journal of the Medical Sciences* for September Dr. D. D. Stewart points out that tuberculosis—acute or chronic—may manifest itself as a splenic lesion for a greater or less period without signs of the disease in any other organ being manifest. He relates the following case. The patient was a single woman, a nurse, aged 29 years, with a good family history. While recovering from influenza she nursed a man suffering from tuberculosis. She ate irregularly and lost sleep. She became ill and had pyrexia and aching in the back. She had a chill every day, the temperature ranged between 101° and 103° F., and she was thought to be suffering from typhoid fever. On April 18th, the tenth day, she was admitted to hospital. The spleen was markedly enlarged, reaching as high as the sixth intercostal space and being palpable below the ribs. The tongue was clean. Daily examinations of the lungs were negative. The temperature showed morning exacerbations and evening remissions and ranged daily from about 101° to 104°. Repeated examinations of the blood showed the absence of Widal's reaction and of malarial plasmodia. On May 14th two small glands were felt in the left supra-clavicular fossa. Ophthalmoscopic examination showed some congestion of the retina. Towards the end of May fine râles were now and then heard in the lungs. In June vomiting occurred daily; she had headache by day and delirium by night. Frequent twitchings of the upper limbs occurred and were accompanied by a harsh cephalic cry. The *tache cérébrale* was well marked. She died comatose on June 15th. The necropsy showed some miliary tubercles in the brain, lungs, liver, and kidneys. The spleen was four times its normal size and studded on its peritoneal coat with elevated yellow tubercles of the size of a large pea. On section the whole organ was found to be a mass of tubercles varying in size from a pin-point to four

millimetres in diameter. About one-half of the spleen had been converted into a caseating mass. The advanced tuberculosis of the spleen, as compared with other organs, causes Dr. Stewart to regard the case as one of primary tuberculosis of the spleen. Scharold has recorded the case of a convict apparently in good health and employed in out-door work who was suddenly seized with symptoms of an acute general infection.<sup>1</sup> There were high fever, headache, cough, epistaxis, diarrhoea, delirium, and general cyanosis. The spleen was greatly enlarged. Death occurred on the seventeenth day. The necropsy showed miliary tuberculosis limited to the spleen. Cases of presumed chronic primary tuberculosis of the spleen have more commonly been observed than acute cases such as those just described.

#### ST. THOMAS'S HOSPITAL: CONSECRATION OF THE CHESELDEN LODGE OF FREEMASONS.

THE consecration of the Cheselden Lodge, No. 2870, took place in the Governors' Hall of St. Thomas's Hospital on Monday, Nov. 4th. The Most Worshipful Grand Master the Duke of Connaught and Strathearn, K.G., who is the President of St. Thomas's Hospital, had signified his intention of being present at the ceremony of consecration and of performing a most important part of the ceremony himself. Most unfortunately, however, for the founders of the lodge and their guests a dense fog prevailed, which rendered it impossible for the Duke of Connaught to reach the place of meeting and a message by telephone was received to say that he could not come. In his regrettable but unavoidable absence the ceremony of consecration was most impressively carried out by V. W. Bro. E. Letchworth, F.S.A., Grand Secretary, assisted by the following Grand Officers: W. Bro. Clement Godson, M.D., P.G.D. (as S.W.); W. Bro. Alfred Cooper, F.R.C.S., P.G.D. (as J.W.); V.W. Bro. Sir Borradaile Savory, Bart., Grand Chaplain; V.W. Bro. W. C. R. Bedford, Grand Chaplain; V.W. Bro. Frank Richardson, P.Dep.G. Registrar (as acting D.C.), assisted by W. Bro. Fitzroy Tower; W. Bro. Woodhouse Braine, F.R.C.S., S.G.D. (as I.G.); and W. Bro. W. Walmsley-Little, Mus. Doc. G.O. There was a very large and distinguished gathering, both of Grand Officers and of well-known members of the medical profession and others interested in hospitals in general and St. Thomas's Hospital in particular, including R.W. Bro. the Lord Mayor, P.G.W.; R.W. Bro. the Earl of Templetown, Grand Senior Warden; R.W. Bro. F. S. W. Cornwallis, Grand Junior Warden; R.W. Bro. G. Richards, D.M.G. Transvaal; R. W. Bro. Colonel John Davis, Provincial Grand Master of Surrey; and W. Bro. Sir W. Mac Cormac. Doubtless the fog was responsible for keeping many others away, but despite the weather the attendance was very large. The officers of the Lodge are as follows: W. Bro. Thomas Wakley, Jun., L.R.C.P. Lond., P.P.G.D., Surrey, Worshipful Master; V.W. Bro. Alderman W. Vaughan Morgan, P.G. Treas., I.P.M.; Bro. H. H. Clutton, F.R.C.S., Senior Warden; W. Bro. G. Crawford Thomson, M.D., Junior Warden; Bro. Sydney Phillips (Steward of St. Thomas's Hospital), Treasurer; Bro. Charles R. Box, M.D., F.R.C.S., Secretary; Bro. W. S. Colman, M.D., F.R.C.P., S.D.; Bro. T. G. Nicholson, M.D., J.D.; W. Bro. Samuel Hague, M.D., P.P.G.D.C., Middlesex, D.C.; W. Bro. L. A. Bidwell, F.R.C.S., I.G.; W. Bro. H. J. Pringley, M.R.C.S., L.R.C.P. Lond. and W. Bro. W. H. Lawrence Copeland, M.D., Stewards. At the conclusion of the ceremony the brethren made their way as speedily as the fog permitted to the Trocadéro Restaurant, where the banquet was held, the number of members and their guests amounting to about 120. V.W. Bro. the Grand Secretary, in responding to the toast

of "The Consecrating Officers," mentioned that he had that morning seen the M.W. Grand Master who had said that he was looking forward with pleasure to the meeting that evening; and it was most unfortunate that the density of the fog had rendered it impossible for His Royal Highness to reach St. Thomas's Hospital in order to carry out his intention of being present. The Worshipful Master, in replying to the toast of his health, which was proposed by V.W. Bro. Vaughan Morgan, gave a few particulars concerning the name of the Lodge. The Hospital Lodges which preceded it had, he said, followed no uniform plan with respect to their names. Some—St. Mary's practically and classically, and Middlesex and London absolutely and in the vernacular—had very naturally adopted the actual names of the hospitals. They had been precluded from following such a course, for they had found that there was already a St. Thomas's Lodge in existence—a St. Thomas's Lodge, moreover, which was very closely connected with St. Thomas's Hospital. This Lodge held its meetings at Tibshelf in Derbyshire, on an estate (in a colliery district) which was one of the hospital's most valuable properties, the hospital authorities being Lords of the Manor, and the greater part of their possessions there having been derived under a Charter of Edward VI., and having belonged to the ancient hospital of the Savoy. St. Bartholomew's, the pioneers of modern Hospital Lodges, had taken the name of their great founder Rahere, and Charing Cross had taken the very appropriate and pleasing name of "Chère Reine" in double allusion to Queen Eleanor, one of whose crosses was erected at the village of Charing, and to our late beloved Queen Victoria, who was their patroness. The Founders of the Lodge, which had been that day consecrated, had called their Lodge after the name of an illustrious anatomist and surgeon, William Cheselden, the introducer of the operation of lateral lithotomy, who was a member of the medical staff of St. Thomas's Hospital from 1718 to 1738. He (the speaker) had been endeavouring to discover whether Cheselden was a Freemason, but was unable to arrive at any definite conclusion. He had, however, in the course of his inquiries, had his attention directed to a trustworthy record of Sir Robert Clayton (who was President of the hospital in 1691) having summoned a Lodge of his Brother Masters to meet at St. Thomas's Hospital in 1693 to advise the Governors as to the best design for rebuilding the hospital, and of a Lodge in connexion with the hospital having continued long afterwards. So they had done no new thing that day in holding a Masonic Lodge in St. Thomas's Hospital. They had but renewed an association after the lapse of 200 years. Although Cheselden perhaps had not been associated with Freemasonry in the past he hoped that they would be able to win for the Cheselden Lodge—and so for his name—a reputation as honourable in Freemasonry as he won for himself in surgery and anatomy. The Worshipful Master in proposing the toast of "The Officers" took the opportunity, having previously referred to the great assistance that had been so willingly given by the Immediate Past Mast. V.W. Bro. Vaughan Morgan, of calling attention to the invaluable services that had been rendered in the Foundation of the Lodge by Bro. Clutton, Bro. Crawford Thomson, Bro. Sydney Phillips, Bro. C. R. Box, Bro. Colman, and Bro. Nicholson, the work of the Secretary being particularly arduous and responsible, though all had lent themselves devotedly to the work. An excellent programme of music under the superintendence of the Grand Organist, W. Bro. W. Walmsley-Little, enhanced greatly the pleasure of the evening, the only regret being that owing to the length of the proceedings and the delays due to the fog some of the items had unavoidably to be omitted. It should be added that H.R.H. the Duke of Connaught was graciously pleased to honour the Cheselden Lodge by becoming its first honorary member.

## THE REPORT OF THE DEPARTMENTAL COMMITTEE ON FOOD PRESERVATIVES.

So far as we can ascertain this report has not yet been made public, although it is said that it was placed upon the table of the House of Commons some time ago. Yet we doubt whether any subject in home affairs presses more urgently for definite legislative action than that relating to the use of preservatives and colouring matters in food. Mr. Chaplin, in the House of Commons on July 28th, 1900, held out the hope, pending further experiments by the committee, that their report would be presented by the end of the year (1900). The committee were appointed in July of the previous year, over two years ago, and we have consistently reported their proceedings in our columns since that time. The last notice we published of these proceedings was in THE LANCET of Oct. 6th, 1900 (p. 1024), when we were able to state that the committee before pledging themselves to a definite conclusion were anxious to collect information abroad as to the use of antiseptics in food and their control, and that for this purpose some of the members of the committee had visited Denmark and Ireland. There has, therefore, been a clear year from that date to the present during which a report might have been published. The result of this unnecessary and vexatious delay—for we can see no reason for it—has been to interfere seriously with the efficient administration of the Acts which provide for the supply of pure and unadulterated food. These questions magistrates and counsel alike have maintained cannot be decided until the decision of the experts appointed by the Government is known. We are still without this report, and accounts of impotent proceedings to stop the use of preservatives in food still appear from time to time in the daily papers. This is a most unsatisfactory position alike to the trader and to the public. Those, however, whom legislation on this subject most intimately concerns will perhaps have noticed a significant incident in the proceedings of a case reported recently. It appears that one of the members of the Departmental Committee appointed to inquire into the use of preservatives and colouring matters in food was ready to be called for the defence in a case in respect of the use of boric acid in butter. Now, unless there proves to be a dissentient opinion or a minority report in the recommendations of the committee it is pretty evident from this that under some conditions at any rate the use of preservatives, or certain of them, is to be countenanced. We trust that the report, if it has been placed upon the table, will be published without further, and as it seems to us quite unnecessary, delay.

## THE FIRST SUSPECTED CASE OF PLAGUE IN LIVERPOOL.

We have received the following report of the first suspected case of plague in Liverpool from Dr. William Alexander, surgeon to the Liverpool Workhouse Hospital. A youth was admitted to the medical wards of the workhouse hospital with high temperature in the early part of October. It was subsequently discovered that he had strained himself in playing football. On examining the groin a number of enlarged glands were found. The traumatic nature of the disease was accepted; and as the temperature rose to a very high degree and the glands became still more swollen he was transferred to the surgical wards, where Dr. Alexander cut down upon the swelling and removed four or five enlarged glands. He was struck by the amount of œdema around the glands, also by the absence of suppuration and by the dark grey surface exposed when the glands were cut. The bacteriologist (Dr. A. S. Griffith), who was present at the operation, was requested by Dr. Alexander to examine the glands in order to ascertain what microbes were the cause of the disease, Dr. Alexander remarking

at the time in a jocular manner that it might be a case of plague. Dr. Griffith made the requisite investigation and found the pathogenic organisms, and there is very little doubt that the case was one of plague. The patient died 24 hours afterwards and Dr. H. Peet, one of the house surgeons, who made the post-mortem examination, reported that he only found the results produced by high temperature without any other serious lesion. No source of infection could be found to account for the disease, and although a great many people were exposed to contact with the patient whilst in the hospital no other case has since arisen. This case shows how insidious a disease plague is and how difficult it is to guard against early cases when there is no suspicion that the disease is in the neighbourhood.

## THE INCORPORATED SOCIETY OF TRAINED MASSEUSES.

MASSAGE when practised by competent persons acting under the immediate supervision of members of the medical profession plays an important part in the treatment of a variety of complaints. On the other hand, the experience of most countries has shown that several serious evils are certain to ensue when irresponsible persons are allowed to advertise themselves as prepared to apply massage to patients. Many of our readers will therefore be pleased to hear that a number of ladies have formed a society which holds periodical examinations in the theory and practice of massage, and the successful candidates, after signing a declaration that they will conform to the rules, receive the certificate of the society and their names are placed on its roll as certificate-holders. Certificate-holders over the age of 21 years are eligible for election to be members of the society. The objects of the society include the following points: (1) to improve the status and training of masseuses; (2) to provide for the holding of examinations and the granting of certificates of qualification; (3) to establish a registry; and (4) to arrange lectures, to provide a reference library, &c. All members, associates, and certificate-holders are required to abide by the following rules: (1) not to undertake any cases of massage except under the direction of a registered medical practitioner, and in regard to massage for men to act in accordance with the by-laws of the society; (2) not to advertise in any way whatever except in recognised medical papers; and (3) not to sell goods to patients in a professional capacity. The movement has received marked support from the medical profession, upwards of 70 of the members of which, including several medical ladies, have expressed their approval of the aims and principles of the society. The society neither fixes nor controls the working fees of its members. Its offices are at 12, Buckingham-street, Strand, London, W.C.

## SMALL-POX AND VACCINATION IN PHILADELPHIA.

LIKE London the city of Philadelphia is troubled with a small-pox epidemic which is scattered in all directions, though there are a greater number of cases in the north-western districts. According to the Bureau of Health there were up to the middle of October 376 cases of small-pox; 205 cases were still under treatment and there had been 48 deaths from that disease. Dr. Martin, who had been attending many patients, had himself contracted small-pox. So far this is but a small epidemic as compared with that of 1871-72 when there were no less than 15,629 cases and 4453 deaths. But since that date the acceptance of vaccination at Philadelphia has been almost unanimous. It is said that the small-pox was introduced by some negro labourers who came from the South, while others attribute the mischief to returning troops from Cuba and Manila. The fact is that at present small-pox prevails in a great

many towns both of Europe and America. During the first six months of the present year 1680 cases were reported in New York city, but good hopes are entertained of ability to cope with the evil. In 1871-72 at Philadelphia, out of 15,629 cases 13,252 were treated in their own homes. To-day practically all the patients are removed to the hospital. Then the Board of Education has issued instructions to exclude from all public schools children who cannot show good vaccination marks. President Good, of the Bureau of Health, has publicly declared that the hospitals contain only two classes of patients, those who are unvaccinated and those who were only vaccinated in their infancy and so long ago that the protection has partially or completely worn away. Not a single patient had been admitted who had been recently and successfully vaccinated. As a case in point, President Good mentioned a father, mother, and six children who were admitted to the small-pox hospital. The parents were vaccinated in infancy and as the protection had somewhat diminished they had a mild attack of varioloid. Their four youngest children were unvaccinated and they had unmodified small-pox. The two other children having reached the school-age were vaccinated before they could be admitted to the school. They were the only members of the family who did not take the small-pox, though they were freely exposed to the infection for about four weeks. A few parents are now being prosecuted for not sending their children to school, the fact being that these children had been refused admittance to the schools because they were not vaccinated. But these are isolated cases—the immense majority of the population are eagerly seeking the protection which vaccination affords, and it is estimated that within the last few weeks 150,000 persons have been vaccinated in Philadelphia. The daily average output of vaccine tubes by the Bureau of Health is 5000, and the latest advices record that the epidemic is decreasing.

THE annual dinner of the staff and present and past students of the Royal Dental Hospital of London will be held on Saturday, Nov. 23rd, at the Hotel Métropole (Whitehall Rooms) under the presidency of Mr. W. H. Woodruff. Gentlemen either now or formerly connected with the hospital or medical school who may through inadvertence not have received special notice, and who desire to be present, are requested to communicate with the Dean at the Royal Dental Hospital, 32, Leicester-square, London.

A LECTURE will be delivered by Dr. H. E. Leigh Canney, at 3 P.M. on Tuesday, Nov. 12th, at the Royal United Service Institution, Whitehall, S.W., on Typhoid, the Destroyer of Armies, and its Abolition. The lecture will be followed by a discussion in which it is hoped that the subject will be also specially considered in its bearing on transport and the responsibility of officers generally. The chair will be taken by Sir William Broadbent.

THE fact that the King, on the occasion of the visit of their Royal Highnesses the Duke and Duchess of Cornwall and York to His Majesty's dominions beyond the seas, has been pleased to approve of the honour of Knighthood being conferred by His Royal Highness upon Dr. James Graham, Member of the Legislative Assembly of the State of New South Wales, Mayor of the City of Sydney, has been gazetted.

THE annual general meeting of the Royal London Ophthalmic Hospital Guild will be held on Monday, Nov. 11th, in the board-room of Moorfields Hospital, City-road, E.C., at 3.30 P.M., Adeline, Duchess of Bedford, in the chair. After the meeting the hospital will be open for inspection by members of the Guild, and the committee

will cordially welcome the presence of any friends invited by the members.

By permission of the Duke of Westminster, a public meeting will be held at Grosvenor House, Upper Grosvenor-street, W., at 3.30 P.M., on Wednesday, November 20th, under the chairmanship of the Right Honourable the Earl of Meath, to promote the objects of the Coal Smoke Abatement Society.

THE second annual dinner of the Otological Society of the United Kingdom will be held on Monday, Dec. 2nd, at the Café Monico, Shaftesbury-avenue, at 7 for 7.30 P.M. The President, Sir William Dalby, will be in the chair.

PAPERS which should lead to an interesting discussion on the various aspects of small-pox will be read at the Hunterian Society on Wednesday next, Nov. 13th.

## THE REPORT OF THE NAVAL DIETARIES COMMISSION.

(FROM A CORRESPONDENT.)

"When sailors lived on mouldy bread and lumps of rusty pork, No Frenchman dared his nose to show between the Downs and Cork; But now that Jack gets beef and greens, and next his skin wears fannel, The Standard says we've not a ship in plight to keep the Channel."  
—G. O. TREVELYAN.

THE student of dietetics who takes in hand the recently issued bluebook (Cd 782) on "Navy Rations" cannot but compare it unfavourably with C 9166 of 1899 on "Prison Dietaries." In the first place it does not think his thoughts or talk his language; probably that is because the Committee were made up of six laymen and but one medical man, while the earlier committee had three experts and but one layman; and secondly, there is very little of scientific method about the report. The report boasts that investigations of nutritive values have been neglected, and, apparently unhelpt by science, from a mass of gossip and opinion stated the Committee have managed, with the proverbial luck—which is only another name for the sagacity—of the smart sailor, to evolve, without telling us how or why, a very good new scheme of diet which only requires a little further definition to make it an ideal diet for the navy in peace time. As to war time, it is less certain and information would be welcome from the laboratory of the Royal College of Physicians of Edinburgh or from other authority as to the composition and force value of the preserved and salt meats which are to be the food of the seaman when his day of action comes—when we want him most, and when the canteen on board is closed or empty, and only the service ration is available to feed his stomach for the fight.

The first and most obvious subject for inquiry is the meaning attached by the members of the Committee to the word "real." They twice state that "no real dissatisfaction in regard to the present navy ration exists," but they record that "a generally expressed wish of the men was that more potatoes should be supplied"; so it seems that "a generally expressed wish for change" does not appear to the Committee to be the result of "real dissatisfaction" with things as they are. "Real" here seems to mean "intense," "bordering on the mutinous." Again, biscuit is one of the articles of the ration for savings in which a man gets less money than the article costs (p. 70), yet though the savings price is against the sailors the Committee tell us (Appendix I., p. 50) that the men save 94·7 per cent. of the biscuit; they only take up and eat 5·3 per cent. of this form of food in regard to which (p. 17) it is said that "no real grounds of complaint exist." What a pity the Committee did not tell the unreal grounds of complaint if they probed deep enough to find them out from shy or suspicious witnesses. It is to be presumed that the relation of the "handy man" to navy biscuit is that of the poet to Dr. Fell:—

"The reason why I cannot tell;  
I do not like thee, Doctor Fell."

Speaking of Appendix I. two puzzles most difficult to solve may be mentioned:—1. Why were the gunnery ships (p. 48) though always in harbour supplied with biscuit only but no bread? 2. How did the men in the boys' training ships (p. 51) manage to save 121 pounds of preserved potato out of the 115 pounds allowed them? And how does 121 come to be 100 per cent. of 115? There is another curious question as to the meaning of phrases or the accuracy of printed statistics. "Preserved potato is very seldom taken up" (p. 19)—10 per cent. only (p. 51). Again on p. 17, "Soft bread is very seldom taken up." This time p. 50 shows that 44 times in 100 is counted by the Committee as "very seldom," a phrase to which they have clearly attached a private interpretation.

The position, then, as stated in the report (which is of course based on the statistics in the Appendix) and in the statistics, appears to be that the men will scarcely touch the biscuit "in regard to which no real grounds of complaint exist," but that they seem to have a considerable fancy for the bread which "is very seldom taken up." Do the Committee whose report and statistics have led to such opposite conclusions merit our blind confidence? Any man-o'-war's man will tell us that the first improvement he wants in the ration is fresh bread at sea. If not, why are ships lying in harbour abroad so anxious to send fresh bread off to the lower deck messes of a favourite or popular ship as it is seen coming in after a sea cruise? They all want bread at sea in lieu of biscuit; it may be that they cannot have it, but the report gives little evidence that the Committee have faced the question fairly. Bread is issued at sea to the French and German navies and bread has been baked at sea for the men in small craft in our own navy. Was it not Lord St. Vincent who said that anything could be done on board a ship? And now that biscuit is to be packed in tin-lined cases so that it will not deteriorate, the force of the argument of the Committee against the issue of bread at sea owing to the consequent waste of unused biscuit is greatly weakened.

No remarks are made by the Committee on refrigerating chambers in ships, though our navy profited much by them in Manila and Taku through the kindness of the American admirals. I hear that small refrigerating chambers are being built into the newer battleships.

The Committee are quite content with the salt-preserved meat supplied in the sea ration (which, be it remembered, is also the war ration), but surely salt beef, excellent as is the meat supplied to the service when killed, is a little behind the age now. Even if it were lightly corned at Deptford, and then tinned, a more satisfactory ration could be produced.

There is no reference made in the report to the food of men landed from their ships in war. Officers who have recently served in China and South Africa condemn the service ration, in the absence of associated vegetables or condiments, as intolerably unpalatable, and recommend some form of Maconochie's ration—beef and peas, &c. The Russians had a somewhat similar ration in China and were supposed to have more tasty food than our people. Sapidity is of great importance, and it is also of importance that as many of the constituents of the meal as possible should be in one tin to save trouble in the bivouac. It is a pity that no means have been discovered to make possible a daily issue of butter or cheese. Cheese is very apt to spoil and butter looks horrid in the tropics; margarine is nearly as good and is less expensive. Sailors have been known to prefer it to butter in the tropics when both were provided free. The only real want in the ration as now recommended is in the fats, and butter is served out daily in the German navy and at specified intervals in the United States navy. The two ounces of jam will make a good substitute and it is well to see the sugar increased.

The alterations of the meal hours are all improvements, but of course they are only to be legalised now, they have been established for years. The changes in meal hours and improvements in the ration may brighten the lot of patients in the naval hospitals.

There is no mistaking the gusto with which the executive officers on the Committee turned from the arid wastes of carbohydrates and hydrocarbons to the really practical question of altering the ship's routine so as to fit in the meal hours of all the reliefs quite neatly. Here they enter into a minute detail which is rather lacking in the more purely scientific part of their report. There was no engineer or marine officer on the Committee, so perhaps it is not surprising that although the "youths" from 16

to 18 years of age who enter on board the *Northampton* have a specially increased dietary, no special feeding is provided for recruit stokers who enter at 18 years of age or for marines who join at the age of 17 years. This is a great want. These youngsters are growing, and besides are probably half starved when they join—indeed, that is in many cases why they join—and the service would get much more good out of them in those very important days of their early recruit drill if they were sufficiently fed. Besides, they would be more contented, would get into less trouble, and would less frequently desert, so some would be saved ruin of character, imprisonment, and wrecked careers.

The only scientific information based on accurate recorded observation about the feeding of the seamen brought forward in the report is in Appendix IV., which tells the amount of food consumed by men at sea when they had a canteen and when they had not. When without a canteen they ate 2·3 pounds a day; with a canteen they ate more than 3·2 pounds. This suggests that there may well be "real dissatisfaction in regard to the present navy ration," which is now practically the same as it was 25 years ago when these observations were made by Inspector-General Walter Reid and when the men obviously desired a ration over one pound a day larger than that provided by the service. By the way, has the Naval Medical Department no later evidence than this to offer us?

Mention of the Naval Medical Department recalls the fact that, according to the statement of the Committee on p. 6, "in ordinary circumstances every officer or man is either victualled in kind, or if the duties he is called upon to perform necessitate his living ashore he is paid an allowance known as 'compensation in lieu of provisions.'" The treatment of naval medical officers on study leave is *extraordinary*, as they are neither victualled in kind nor are they paid "compensation in lieu of provisions."

The old harbour ration weighed very nearly three and a quarter pounds a day: this was heavier than the ration of any other man-o'-war's man and was most nearly approached by the ration of the Japanese. Foreigners are apt to assert that this great weight of food must unduly tax the digestive energies of our men. They can say nothing against the amount and quality of the work done by the men who receive all this food. The new ration will weigh four pounds. It is not laid down absolutely, variations being permitted on certain points where the further definition to which we referred at the outset is required. If good mutton be issued twice a week the amount of fat in the diet will be satisfactorily increased, and if half of the daily vegetable issue be ordered to be potatoes, or if leguminous vegetables only are allowed to be substituted on a definite scale, the carbohydrates will be always maintained at the high level required. But if the beef were always "trek ox," and if the vegetables were always tomatoes, pumpkins, and cabbage, on the other hand, the diet would fall below what is wanted. (See p. 18: "A generally expressed wish of the men was that more potatoes should be supplied.") In this direction it is to be hoped that the Admiralty will recognise the need for the further definition which we have seen to be necessary. Granting that these regulations, as we have suggested, are brought in, the new dietary will work out as below. The dietary of a convict on hard labour is inserted for comparison:—

	Seaman's diet.		Convict's diet. per day.
	Per week.	Per day.	
	Ounces.	Ounces.	Ounces.
Proteids ... ..	58·58	8·37	6·26
Carbohydrates ...	138·81	19·83	22·63
Fats ... ..	25·42	3·63	3·04
Salts ... ..	8·89	1·27	1·48

So that the new dietary proposed by the Committee works out well in consequence of their practical sagacity and in spite of their scorn for laboratory investigations.

The dietary may also be expressed in weights of nitrogen and carbon—nitrogen 26·2 grammes, and carbohydrates 305·95 grammes—and if these be compared with the diets of various English workmen, as shown by Dr. Thomas Oliver,<sup>2</sup> it will be seen that the diet now proposed for

<sup>2</sup> THE LANCET, June 29th, 1895, p. 1629.

the seaman is theoretically better than that of any English labourer or even of the Ayrshire shepherd or ploughman. This would suggest that in future, except to supply men with relishes suited to each individual, such as a red-herring for this man and a bloater for that, or for providing fresh bread, butter, and cheese, canteens should soon cease to exist. This new naval dietary is not final, but the present Committee are to be congratulated on the advance which they have promoted in the comfort of the men whose interests, as well as those of the public, were committed to their care.

### THE GENERAL MEDICAL COUNCIL: AN OUTSPOKEN VIEW.

A VALUED Irish contributor has sent us the following:—

The present time, when your columns are full of details of the keenly contested election of Direct Representatives, seems to afford a very suitable occasion to discuss the constitution of the General Medical Council.

It is composed of 31 members, 15 from England and Wales, nine from Scotland, and seven from Ireland. As a rule, in Parliamentary representation there is usually some relationship between the population and the number of members, and it must be admitted that on such a basis Ireland is at present over-represented in Parliament. Thus England and Wales, with 495 members, had at the time of the last general election about one member of Parliament to 62,700 of an estimated population; Scotland, with 72 members, had one to about 58,500; and Ireland, with 103 representatives, had one to about 44,200 of an estimated population. If we apply this ratio of representation to the General Medical Council, we find (basing our facts on the last "Medical Directory" and excluding practitioners residing abroad and the naval, military, and Indian medical services) that England and Wales have 15 representatives on the General Medical Council to 23,471 medical men residing within those countries, or one member to about 1564 practitioners; that Scotland has nine representatives to 3569 medical men, or one member to 396 practitioners; and that Ireland has seven representatives to 2575 medical men, or one to about 367 practitioners. The 16 representatives on the General Medical Council from Scotland and Ireland represent numerically 6144 medical men, that is, there is one representative to every 384 practitioners, while in England and Wales there is one member to 1564. To make matters fair, England and Wales should have at least four times as many members on the General Medical Council as she now has—or instead of 15 at least 60. It is probable, however, that to increase the numbers of the General Medical Council would do no good, nor would the present condition of its finances warrant such a course; so if proportionate representation is to have any force, and if England and Wales are to retain their 15 members, then the 16 from Scotland and Ireland should be reduced to four. The first striking peculiarity of the General Medical Council, therefore, is the disproportionate representation of the various parts of the three kingdoms.

The method by which the appointment of the members is carried out is equally anomalous. There are three ways by which a registered practitioner may become a member of the General Medical Council. Firstly, he may be elected to represent some of the corporations (universities, royal colleges, apothecaries' halls, or faculties). Those chosen in this way are the so-called "Corporate Members," and they number in England and Wales nine out of a total of 15, seven out of nine in Scotland, and five out of seven in Ireland. They are elected by the senates or governing bodies of these corporations—a constituency which does not include the graduates or diplomates of these bodies. Secondly, in addition to those Corporate Members who are elected on such a narrow and exclusive franchise, there are other representatives nominated by the King with the advice of the Privy Council. These are life appointments and the holders are practically responsible to no one. There are three Crown representatives appointed from England and one each from Scotland and Ireland, and they are termed the "Crown Nominees." Finally—and this modicum of justice was only gained after a long and keen struggle—there are five members (three from England and one each from Scotland and Ireland) elected directly by the vote of the medical profession. They sit for five years, but are eligible for re-election, and these five gentlemen are styled the "Direct Representatives."

Financially, the General Medical Council is supported by the registration fees compulsorily paid by all members of the medical profession, and yet (contrary to all ideas of modern representative government) they, who supply the sinews of war, are allowed to elect out of a board of 31 members only five to represent them. Such methods of selection of the members of the General Medical Council are totally opposed to all democratic representative principles and also to the feelings, again and again expressed, of the general practitioners of the United Kingdom.

If the mode of election of the members of the General Medical Council is peculiar so is their topographical distribution. Of the 15 members from England and Wales 10 reside in London, five in the provinces outside the metropolis, and Wales has not a single representative at all. In Scotland, of the nine members four reside in Edinburgh, two in Glasgow, one in Aberdeen, one in St. Andrews, and one in Dingwall. In Ireland every one, without exception, of the whole seven members resides in Dublin. Looked at from the point of view of local or topographical representation (the essential element in all modern representative forms of government) Scotland is most fairly treated in its members on the General Medical Council, for not only are the Corporate Members spread over the country, but the Crown Nominee comes from Glasgow, and the Direct Representative from Dingwall in the north. England and Wales have two-thirds of their members from London, but, on the other hand, Cambridge, Durham, Manchester, and Birmingham are represented, and one of the Crown Nominees comes from Leeds. In Ireland there is the most preposterous centralisation of members of the General Medical Council, for not only do the Corporate Members, but also the Crown Nominees and the Direct Representative, all come from Dublin. Thus, looked at topographically, the 414 medical men in Dublin have the whole seven representatives on the General Medical Council, while the remaining 2161 practitioners in Ireland are totally unrepresented on that body. Neither from Connaught in the west, from Munster in the south, nor from Ulster in the north, of Ireland, is there now, or has there ever been, a representative on the General Medical Council. When it is recollected that in population Belfast now exceeds Dublin and that it has the largest medical school in Ireland next to the Catholic School in Dublin, it is surely time that this city should get a representative on the General Medical Council, and that the continued attempt at centralisation in Dublin should cease. Imagine Scotland with every representative on the General Medical Council hailing from Edinburgh and in England and Wales not a member to represent any place but London! Why, one of the chief arguments employed by candidates in their electioneering proceedings, whether when standing for the General Medical Council or the Council of the Royal College of Surgeons of England, is that they do not live in London!

The General Medical Council in its constitution, in the mode of election of its members, and in its tendency to metropolitan centralisation is totally behind the times we live in, and this accounts for the fact that its influence is waning with Parliament and with the nation. It cannot in any sense be regarded as the accredited mouthpiece of the profession, and as a result statesmen pay it no attention. A body more democratically elected, on modern representative principles, must arise before the practitioners of the three kingdoms can hope to have their welfare looked after or their just rights protected.

### MEDICAL STUDENTS AND THE LONDON SCHOOLS.

(FROM A CORRESPONDENT.)

THE reduction in the entry of students in the London medical schools is attracting close attention at the present time, and it has occurred to a correspondent of THE LANCET who is interested in this question to analyse the record of registrations of medical and dental students with a view to ascertain whether any explanation of the falling-off may be found in this interesting record.

The following table shows the registrations of medical

and dental students in the divisions of the kingdom respectively for the years 1899 and 1900—the last returns available:—

	Registered students.			Total.
	England.	Scotland.	Ireland.	
1899 ... ..	1106	588	274	1968
1900 ... ..	855	578	274	1707
Decrease ...	251	10	—	261

From this return it will be seen that whilst the number of Irish students has remained stationary and those in Scotland practically so the English students have decreased by the large number of 251.

A further analysis of the preliminary examinations in arts passed by the students reveals some interesting facts, as the following table will show, viz.:—

	1899.	1900.	Increase.	Decrease.	
<b>Universities:</b>					
Oxford (responsions, &c.) ... ..	23	26	3	—

Universities ...	896	889	—	7	{ Total net decrease, 261.
Other examinations ... ..	1077	823	—	254	
	1973	1712	—	261	

From the above figures it appears that there was a slight diminution (seven) of registrations on university entrance examinations, whilst, omitting colonial and foreign students, there was the heavy reduction of 276 registrations on other examinations. Leaving out of consideration the university

senior local examinations and the Central Welsh Board, which are not taken to any extent by the professional students, we come to what may be called the “minimum” examinations, such as the Oxford and Cambridge junior locals, and schools, examinations and the College of Preceptors in England; the Scotch Education Department examination and the examinations of the Preliminary Institute of Scotland; the examination of the Royal Colleges of Physicians and Surgeons in Ireland, and the Intermediate Education Board of Ireland. When the figures of these “minimum” examinations are further analysed it appears that whilst in England there was a reduction of 312 students, in Scotland there was an increase of 33, and in Ireland an increase of 12. What, then, is the explanation of this disparity? The General Medical Council, it will be remembered, decided to eliminate on Jan. 1st, 1900, from the list of recognised examinations, the second-class examination of the College of Preceptors, an examination well known to be the popular entrance to the two professions in England apart from the universities; and whilst it is not intended to argue either that the second-class examination of the College of Preceptors is a good standard of entrance examination or that the General Medical Council are not right in steadily raising the standard of preliminary education, it is submitted that this arbitrary removal of a popular examination from the recognised list without making provision for some other examination to take its place was calculated to affect injuriously the English medical schools by suddenly checking the supply of entries. Further, the “minimum” examinations in the other divisions of the kingdom are left untouched, with the result that they show an increase in numbers, no doubt owing to some English students availing themselves of the opportunity of passing the examinations in those divisions, most nearly approximating in standard to the hitherto recognised “minimum” standard examination in England; but it is not to be expected, and certainly it is not desirable, that schoolmasters should have to send their boys to Edinburgh or Dublin to pass the preliminary examination.

It is said that the College of Preceptors many months ago expressed their willingness to modify their examinations to meet the views of the General Medical Council, and although it is believed that some negotiations have taken place, nearly two years have elapsed and this disability of English medical and dental students has not been removed. It is well-known that the first-class examination of the College of Preceptors is of a much higher standard than the Scotch or Irish “minimum” examinations, and consequently it is one which can never be a popular entrance examination for the professions. If this disparity is not to continue arrangements should either be at once completed by which the College of Preceptors’ examination is modified to meet the requirements of the General Medical Council so that its standard shall not be higher for medical and dental students nor yet lower than is required of the “minimum” standard examinations in Scotland or Ireland; or, as an alternative, that the Conjoint Board in England should revive the preliminary examinations in arts formerly conducted by the Royal College of Surgeons of England. Now that the Conjoint Board in England have ceased to require their students to be registered there does not seem to be any reason why they should not go a step further and revert to the old system of conducting their own preliminary examination in arts, not with a view to lower the standard of examination, but in order to prevent the recurrence of what certainly appears to be an ill-considered attempt to elevate that standard in one division of the kingdom only.

## THE MIDLAND MEDICAL UNION.

THE annual meeting of the Midland Medical Union was held at the Albert Hall, Nottingham, on Oct. 23rd, Mr. J. G. SHEA, J.P., the President, being in the chair. Letters expressing inability to attend were received from Dr. W. B. Ransom (Nottingham) and Dr. F. Cassidi (Derby). THE PRESIDENT, in a short address, referred to the increase in the work of the union and alluded in detail to matters which had been dealt with during the past year, speaking particularly upon the purpose and scope of the union. The Honorary Treasurer (Dr. F. R. Mutch) presented his

report which showed the funds of the union to be satisfactory.

The Honorary Secretary (Dr. E. H. Houfton of Shirebrook) presented a report of the work done during the past year, the salient features of which were as follows. The report commenced by a short *résumé* of the inception and foundation of the union, which practically commenced its career at Chesterfield on March 31st, 1900. The report of the first year's work showed that the first efforts made were (1) to try to establish a minimum fee of one guinea for midwifery cases; and (2) to establish a minimum rate for friendly societies of 5s. per member per annum for adults and juveniles. In regard to the midwifery question they might say that they had met with conspicuous success, for with the exception of a district in and about Eastwood (Notts) and a few cases involving contract midwifery the guinea fee was now universal throughout the two counties and the only reason why the particular district mentioned was exempt was that one of the practitioners whilst not attending cases for less than this fee himself allowed his assistants to do so. In regard to the contract midwifery question the Union agreed to support any member who cared to apply for the increased rate of payment for these particular cases. Dr. W. C. Rainsbury of Skegby, who held a colliery appointment to the Teveral Colliery Club, commenced to charge the increased midwifery fee and in consequence was threatened with dismissal from his appointment. A deputation waited upon the club committee to point out the reasonableness of the fee and asking them to give the matter their careful consideration. However, they sent Dr. Rainsbury an agreement to sign in which he would bind himself to charge a sum of 10s. 6d. for members' wives attended by him in their confinements. This he refused to do and in consequence was served with three months' notice. The colliery club then advertised for a surgeon and the Union advertised warning practitioners not to accept the post, and through the courtesy of the editors of the medical journals no more advertisements were inserted from the colliery club. The club, however, managed to secure a medical man who agreed to accept the appointment, but from knowledge which came to the club committee a letter was sent to him asking him to come at once and inclosing him three months' notice; in consequence of this he never came to take up his appointment. The result was that after Dr. Rainsbury's notice expired on June 25th, 1901, the club were without a medical officer. This state of affairs had continued up to the present. Dr. Rainsbury had been attending the club members, their wives and children at private rates. They had been informed that the club had secured another medical practitioner who insisted upon being given the appointment of a neighbouring practitioner as well as that of Dr. Rainsbury under the same club committee—a practitioner who had been asked to accept Dr. Rainsbury's appointment and had refused. This practitioner had received three months' notice from the club, but up to date no medical man had arrived to take up his duties. In regard to the friendly society question no very great result could be recorded up to date. The resolution suggesting a minimum of 5s. per member per annum had been resound, except in regard to new clubs or clubs changing medical officers, and a sum of 4s. had been substituted. But before enforcing this the Chesterfield Branch chose delegates to meet delegates from the Chesterfield and District General Friendly Societies' Council to see if affairs could be arranged amicably. Up to date the Friendly Societies Council had offered a sum of 4s. for adult members and 2s. 6d. for juveniles, but this had not been accepted by the Union and the matter was still under discussion. In regard to other questions which had been dealt with by the Union might be mentioned that of the Butterley Company and their surgeons. In this case the company sought to reduce their surgeons' fees, but on a firm front being shown by the surgeons through the Union the question of reduction was dropped. Several cases of difficulty between clubs and their surgeons had also been settled satisfactorily. Mention might be made of many other questions which the Union had dealt with or which were still under discussion; but in summarising the result of the first year's work of the Union they might state that the most pleasing result was the fact that medical men had been brought together in the meetings of the various branches and that in the discussion and interchange of opinion many old difficulties and misunderstandings had been removed and a more cordial professional feeling between neighbouring practitioners had been established. At the commencement they

found a sense of distrust amongst medical men almost universal, but they were glad to state that this was being gradually dissipated; and if no other tangible advantage had been derived the founders of the Union might feel themselves amply repaid for their trouble and work in the fact that they had raised the feeling of *esprit de corps* among the profession in that district.

On the proposition of Mr. W. B. CROSKERY (Eckington), seconded by Dr. W. DUNCAN (Clay Cross), the report was adopted.

On the proposition of Mr. R. NESBITT (Sutton-in-Ashfield), seconded by Dr. RAINSBURY, the following officers were elected: Mr. J. G. Shea, President; Mr. T. Geraty, vice-president; Dr. F. R. Mutch, honorary treasurer; and Dr. E. H. Houfton and Mr. C. J. Palmer, honorary secretaries.

On the proposition of Mr. GERATY, seconded by Mr. R. G. ALLEN (Belper), Mr. G. S. O'Rorke, M.A., solicitor, was appointed general secretary.

On the proposition of the PRESIDENT, seconded by Dr. MUTCH, it was resolved that the following rule should be substituted in place of Rule 4:—

The annual subscription for each member to be 10s., payable in advance on Oct. 1st.

On the proposition of Dr. MUTCH, seconded by Mr. W. E. M. WRIGHT, and after hearing observations from Dr. DUNCAN, Dr. H. J. NEILSON (Bulwell), and Mr. R. G. ALLEN, the following motion was carried as an alteration of the rules:—

(a) Members are asked to guarantee a sum of five guineas, or multiple of five guineas, so that in the event of indemnity being required the money may be called up in the proportion promised.

(b) Subscription to this fund is not compulsory.

(c) In case any member should apply to be indemnified from this fund who is not a subscriber to it the granting of relief to such member shall be left with the president and vice-president to decide whether there are special circumstances entitling the member to such relief.

(d) The control of this fund shall be left with the council of the union.

Addresses were then delivered by Mr. GEORGE BROWN and Mr. GEORGE JACKSON, candidates for election to the General Medical Council as direct representatives, and after the usual votes of thanks the meeting terminated.

## THE FIFTH INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.

HELD AT TURIN, SEPT. 17TH-21ST, 1901.

THE following are some further abstracts of communications made to the above Congress:—

### *The Passage of CO Gas through the Placenta.*

Dr. M. NICLOUX (Paris) referred to the work of Grehan and Guingard on this subject, in which they had administered a mixture of the gas and air to a dog in gestation. The animal died in 35 minutes, and on examining the blood of the foetus it was found to contain six times less CO than that of the mother. His own experiments had been carried out on guinea-pigs and he had examined the effects of a whole series of mixtures of the gas with air, varying in proportion from 1 in 10,000 to 1 in 10. From 1 in 10,000 to 1 in 1000 the content of gas in the foetal blood was identical with that in the maternal, and in both cases was proportional to the amount in the respired air. Above the latter figure the identity disappeared, the blood of the foetus showing a steadily less and less amount as the quantity of CO was increased. Since the maternal and foetal circulations were completely independent and no direct passage of CO-hemoglobin from the one to the other could have taken place, there must have been a dissociation of the CO, and this, he concluded, was effected by the placenta. A similar dissociation was produced by the respiratory organs of a fish which were in every way comparable to the placenta. A carp plunged into a mixture of 120 cubic centimetres of dog's blood charged with CO added to three litres of water, and killed after a variable length of immersion, showed that its blood contained five, six, or even seven times that of the medium in which it had been placed. The respiration of the carp in the mixture did not seem in the least abnormal. It did not appear, however, that Dr. Nicloux had excluded the possibility of another phenomenon, explaining his results

in the two instances cited—viz., the relative affinities of the different media for the gas in question.

*The Working of the Lungs Studied by the Plethysmographic Method.*

Dr. T. G. BRODIE (London) and Dr. W. E. DIXON (London) demonstrated an air plethysmograph which they had adapted to the record of lung movements during respiration and other variations in volume, an artificial inflation being kept up. The experiments of their first series were directed to a study of the effects of nerve excitation and of drugs upon the bronchial muscles. They had found (1) that the vagus nerve contained both constrictor and dilator fibres to the bronchial muscles; (2) that the sympathetic contained no such fibres; (3) that muscarine, pilocarpine, veratrine, and chloride of gold produced constriction of the bronchi (asthmatic effect); and (4) that atropine, curare, and to a less degree chloroform and ether vapours, caused dilatation of these tubes. In a second series of experiments the changes in blood volume were observed both when air freely entered and in the case of a lobule with the bronchus previously plugged. The lung capillaries, it was found, became distended with blood when the aortic pressure rose, whether this rise had been produced by constriction of systemic vessels or by increased cardiac action. Failure of the heart, as a rule, also resulted in their distension. In asphyxia the lung volume increased during the first stage but gradually declined during the second and third stages. Dr. Brodie and Dr. Dixon were not able to convince themselves that any vaso-constrictor fibres were supplied to the pulmonary vessels and considered the results of previous observers on this point inconclusive since the action of cardio-accelerator nerves had not been sufficiently excluded.

*Sensory Nerves to the Diaphragm: their Function in Respiration.*

Professor MISLAWSKY (Kasan) cited experiments in which he had found that stimulation of the central tendon of the diaphragm caused an expiratory arrest of thoracic movements. This effect was abolished by division of the vagus either in the neck or immediately above the diaphragm. Further, excitation of the peripheral segment of a divided phrenic nerve produced an expiratory arrest of thoracic movements at the same time that it caused contraction of the midriff. The former effect was no longer seen after section of the pneumogastric nerves. Professor Mislawsky therefore concluded that the diaphragm must receive sensory fibres from the vagus and that they played a similar rôle in respiration to those supplied by the same nerve to the lungs. He had also stimulated the central stump of the phrenic nerve, but had not obtained results differing from those already well known.

*The "Negative Variation" in a Nerve and the "Action Impulse."*

A most important communication relative to the vexed question of the relationship between the so-called "negative variation" in a nerve and the functional impulse was made by Professor HERZEN and Dr. RADZIKOWSKY (Lausanne). These investigators agreed with Valentin that the two were not one and the same thing but separate phenomena, the first of which accompanied but did not constitute the second. On the other hand, they agreed with Waller that nerves more or less altered were able to manifest the electric change while they were no longer capable of functional activity. To demonstrate their contention Dr. Radzikowsky had made experiments on frogs' nerves slightly anaesthetised or spontaneously dying after removal from the animal. These were described in the *Centralblatt für Physiologie*,<sup>1</sup> and the present communication was supplementary to meet certain objections which had been raised. In the experiments referred to, the sciatic nerve with the gastrocnemius muscle attached was removed from the body, care being taken to sever the peroneal branch of the nerve as low down as possible. The whole was placed on a paraffined layer of cork in a fairly large moist chamber. The sciatic nerve was laid on a pair of Du Bois non-polarisable electrodes connected to an inductorium and the peroneal branch on another pair which led off to a galvanometer. A small capsule containing from two to four cubic centimetres of ether was also brought into the chamber. After a variable time (from 15 minutes to one hour) the muscle ceased to respond, not merely to weak currents sent in from the coil, imperceptible on the tongue, but also to very

strong (unbearable) currents. Nevertheless, with each stimulus sent into the nerve in this condition a negative variation in the branch was shown by the galvanometer. The failure of the muscle was not due to any alteration in the motorial end plates because a weak stimulus applied close up to the muscle by a third pair of electrodes at once set up contraction. The anaesthetised or dying nerve was still able to manifest a negative variation while it was unable to respond by the setting up of an action impulse. A further experiment was now brought forward to support the same view. Professor Herzen had destroyed the irritability of a proximal length of the sciatic nerve by the application of chloralose to it. When excited at this part no contraction appeared in the gastrocnemius muscle, but a deflection of the galvanometer nevertheless occurred. Stimulation of any other part of the nerve caused a response in the muscle. An objection had been raised that the deflection was not due to a true negative variation but to an electrotonic effect. There was only one means of setting this aside—viz., to find some mode of exciting the nerve which did not involve the use of an electric current. This was suggested by an experiment due to Professor Borutau, in which a portion of the sciatic nerve of a frog was exposed to drying till it had completely lost its irritability at the spot exposed. The nerve was then moistened with saline and replaced in the limb, after which the frog was poisoned with strychnine. When the strychnine convulsions came on, the limb in question took no part in the contractions, but if the sciatic nerve was divided and connected up as before with a galvanometer each convulsion was accompanied by a negative variation. Professor Herzen and Dr. Radzikowsky considered that this experiment demonstrated conclusively that an altered tract of nerve is able to allow of the passage of the negative variation, while it is no longer able to transmit a functional impulse; also, on the other hand, that the peripheral irritable part of the nerve propagated the negative variation without entering into activity. The author of this experiment, it was true, drew a different conclusion from it, but while the facts were admitted by both sides time alone would decide which of the two hypotheses was valid.

*The Causes of Muscular Fatigue.*

Professor F. S. LEE (New York) said that there were two recognised causes of muscular fatigue—viz., loss of substance necessary to contraction, and accumulation of the so-called fatigue products. In his present research he had paid chief attention to the former. Phloridzin was administered to cats for a length of time, the result being that the animals became muscularly very weak, while at the same time, as was well known, a severe glycosuria was established. Single muscles when removed from the body only gave a few contractions, and graphic records of these revealed a condition of pronounced fatigue. This was not due to any direct toxic effect of the substance upon the muscles. The drug, however, robbed the body of carbohydrate material both in the loose form as well as that combined in the proteid molecule. Hence the supposition arose that normal muscular fatigue was associated with loss of carbohydrate from the muscles. This was strengthened by the fact, which he had discovered, that when prolonged phloridzin poisoning was followed by the administration of dextrose the contractility of the muscles was rapidly restored. Various considerations led him to believe that in normally induced fatigue, there was a first stage (simple fatigue) caused by the accumulation of fatigue stuffs, followed by a later stage (exhaustion) due chiefly to the loss of carbohydrate substances. Professor Lee admitted, in the discussion which followed, that he had made no comparison between the degree of fatigue and the output of sugar in the urine, nor had he estimated the content of glycogen in the muscles at different stages. Nevertheless, in the light of the restoring effects which dextrose exerts upon the fatigued and excised heart, as shown by Locke, and in view of Prevost's results with regard to influence of these substances in aiding re-establishment of cardiac action in asphyxiated animals, both of which have been already referred to in these abstracts, it would seem that Professor Lee's views are probably correct. Professor LEE had also noted, in conjunction with Mr. C. C. HAROLD, that the muscles of phloridzinised animals rapidly passed into rigor after death. But if dextrose had been given before the animals were killed the onset of rigor was considerably delayed. These observers concluded, therefore, that absence of carbohydrate favoured the onset of rigor and

<sup>1</sup> *Centralblatt für Physiologie*, August 17th, 1901.

that in this particular there was an antagonism between rigor and contractility.

*The Action of Alcohol on Muscular Activity.*

Professor LEE and Dr. W. SALANT (New York) gave an account of experiments in which they had injected alcohol of varying strength into frogs in quantity proportional to their weights. In each case one gastrocnemius was protected from the influence of the substance, and the work which this was able to perform was contrasted with that of the opposite leg. In quantities of half a minim of 10 per cent. solution per gramme of weight the alcohol had no effect. In larger doses (from one minim to four minims of 10 per cent. solution per gramme) the amount of work was increased sometimes more than 100 per cent., while in still larger quantities exactly the opposite effects were observed. It was uncertain whether the results were due to direct action of the alcohol on the muscle protoplasm or on the intramuscular nerve terminations.

*Demonstrations of Instantaneous Micro-photographs of Living and Fixed Muscular Fibres of Hydrophilus.*

Professor HÜRTLE (Breslau) explained attempts which he had made to study the contractile phenomena of muscular fibres by means of instantaneous micro-photographs. At first he had confined himself to living fibres, but later he found it necessary to compare his results with fixed and stained preparations. The photographs were taken partly in ordinary light (exposure, 0.012 second) and partly in polarised light (exposure, 0.024 second). His chief conclusions were: (1) that within the wave of contraction the striation was closer and sharper; (2) that in polarised light a homogeneous band or space preceded the contraction wave, but whether this was due to accumulation of sarcoplasm or to a loss of the power of double refraction in the sarcous substance (a possibility indicated by the appearance of fixed preparations) was doubtful; (3) that in fixed fibres both the transverse and longitudinal striation were more obvious than in the living; and (4) that during contraction the nuclei shortened and became spiny or crumpled. The shortening, however, was an active, not a passive, event, since its extent was not proportional to the shortening of the whole fibre.

*The Relation Between the Thyroid Gland and the Parathyroids.*

Professor E. GLEY (Paris) said he could not agree with those experimenters who maintained that there was complete independence of function between the thyroid and parathyroid glands. In support of functional association he adduced the following evidence: 1. Physiological.—Whilst some animals survived complete removal of the parathyroids others presented progressive nutritive disturbances similar to those which followed complete thyroidectomy. He had observed this not alone in the dog but also in the cat and in the rabbit. 2. Chemical.—The parathyroids contained iodine just as the thyroid did and the importance of iodothyron had now been admitted. 3. Histological.—Edmunds had shown that removal of the parathyroids was followed by hypertrophy of the thyroid which revealed itself in an increased vascularity and development of embryonic tissue. With these there was disappearance of the colloid substance, as had previously been observed by Lusena and others. Conversely, extirpation of the thyroids produced alterations in the structure of the parathyroids.

*Complete Removal of the Thyro-parathyroid Organs from Dogs Fed on Bromated Fats.*

Dr G. CORONEDI (Sassari) gave the histories of two dogs which he had fed on bromated fat for different periods of time before the complete extirpation of the thyro-parathyroid apparatus. The first had been fed on bromated foods for 14 days and had received in all 22.6 grammes of bromine. Soon after the operation mild symptoms characteristic of the removal were seen, but these passed off and the animal regained perfect health, living for 71 days. Towards the end of this period grave symptoms of cachexia supervened, from which it died. The second dog was operated upon in April of the present year. It had been fed on bromated fat for 26 days previously, receiving in all 36.21 grammes of bromine. It also showed mild symptoms in the early period, from which it recovered completely, and was then alive and in perfect health. The parts removed in each case were exhibited to show that the extirpation was complete. A photograph of the second animal was also shown. Dr. G. Marchetti (Florence) had assisted in the investigation, which was not yet completed.

*Heterogeneous Thyroid Grafting.*

Dr H. CHRISTIANI (Geneva) said that he had previously

succeeded in obtaining permanent and functionally useful grafts of thyroid glands transferred from one animal to another of the same species. In his later work he had endeavoured to find out whether effective transplantation might not be carried out between animals of different species, and if so how far apart might the zoological relationship be, without barrier to success. Systematic attempts were made on various vertebrates of different classes, orders, families, genera, species, and varieties. Grafts did not succeed between animals very widely separated in the scale, such as classes and orders; some were successful between families; still more and better grafts were obtained between genera; and almost constant success was achieved between different species and varieties. His general conclusion now was that for successful thyroid grafting the animals need not be of the same species as he had previously supposed. The grafts could succeed even between those of different families. The transplanted tissue in the latter cases, however, seemed to have less vitality.

*On Effects of Suprarenal Extract not Hitherto Observed.*

Professor J. N. LANGLEY (Cambridge) described the following effects of suprarenal extract not previously observed by others. 1. Secretion of the salivary and lacrimal glands and of various mucous membranes. The effect on the salivary secretion was at first accompanied by constriction of the gland blood-vessels, but later by slight dilatation. Suprarenal extract and atropin had a mutually antagonistic influence on this secretion, much like pilocarpine and atropine. 2. An increase followed by a decrease of bile secretion. 3. Inhibition of the contractile movements of the gall-bladder. 4. Inhibition of the cardiac sphincter of the stomach (rabbit) and of the walls of the stomach (rabbit and cat). 5. Slow constriction of the pupil in the dog. 6. Contraction and pallor of the uterus, vas deferens, and seminal vesicles. 7. Dilatation with pallor of the lower end of the rectum and internal sphincter of the anus in the rabbit and slight contraction and pallor in the cat and dog. In nearly all cases the suprarenal extract produced an effect upon a given tissue similar to that caused by excitation of its sympathetic nerve, and in no case did it excite an effect similar to that produced by the cranial or the sacral autonomic nerve, as the case might be, with the possible exception of constriction of the dog's pupil. Notwithstanding, the action upon the tissues appeared to be a direct one and not occasioned through the medium of sympathetic nerve-endings, for after degeneration of the post-ganglionic fibres of the cervical sympathetic in the cat the extract produced its usual effects on the eye, the submaxillary gland, and the hairs of the face. The effects of the extract on salivary secretion and on the cardiac sphincter were demonstrated.

*Diffusion Towards the Eye of Substances Injected in the Temporal Region.*

Dr. GAETANO VINCI (Messina) said it was recognised as a clinical fact that when small doses of strychnine were injected subcutaneously in the region of the temple they acted on the eye of the same side, increasing the acuteness and enlarging the field of vision. He had therefore made experiments to determine whether soluble substances injected in this way made their way into the eye by a process of diffusion without entering, or before they entered, the circulation. Three series of experiments had been carried out, in the first of which solutions of iodide of potassium or sodium, of salicylate of sodium, and of ferro-cyanide of potassium were employed. The doses ranged from 0.2 gramme to 0.5 gramme dissolved in from two to three cubic centimetres of distilled water. After a period of from half an hour to one hour the rabbits or dogs were killed by pithing and the eyeballs were enucleated. Test reagents—starch solution, chlorine water, or nitrous acid and ferric chloride respectively—were now dropped into the orbital cavity, when the appropriate colour reaction was obtained, but on the injected side only. The colour, however, was limited to the outer wall of the orbital and to the outer half or two-thirds of the globe of the eye. In the second series 0.5 gramme doses of iodide of potassium were injected in the same way, but the eyeballs were opened and calomel powder was strewn in the interior. The mercurous chloride became converted into the iodide in both eyes, but always from four to eight minutes sooner on the injected side. This latter was to him a trustworthy indication that the substance had not entered by way of the general circulation. Dogs were employed for the third series of experiments, the animals being anaesthetised with chloroform and morphine. From 20 to 30 minutes previously to the

anæsthetisation 0.5 gramme doses of iodide of potassium or of salicylate of soda in a few cubic centimetres of distilled water had been injected into the temporal subcutaneous tissue. Hypodermic needles were now inserted through both corneæ into the anterior chamber of each eye. The outer ends of the needles were closed with small wooden stoppers. From time to time a drop or two of aqueous humour was allowed to escape and to fall into a little of the appropriate test reagent. As a method of demonstration the results could not have been more brilliant. A positive reaction was invariably manifested on the injected side from three to five minutes before the other. Evidence of the entry in this way of ferro-cyanide of potassium or of atropine or strychnine was not obtained. Dr. Vinci concluded, therefore, that soluble substances injected into the temporal region were able to penetrate ultimately into the interior of the globe of the eye by the simple physical process of diffusion.

## Looking Back.

FROM

THE LANCET, SUNDAY, NOV. 9, 1823.

### Acupuncture.

MUCH has lately been said of the efficacy of this remedy in various affections; and well-marked cases in which it has been decidedly beneficial, have been published to the world. In rheumatism, trismus, anasarca, it has been tried, and with success. The facility with which it may be used, leads us to hope that this remedy may meet with a trial from many intelligent practitioners, who may give to the profession a fair and important result of their observations. Acupuncture is a remedy of very ancient date. In the philosophical transactions for 1683, is a notice of a book written by Dr. Ryne, in which an account is given of the pathology of gout, and the various means that the Japanese made use of at that time in the treatment of their complaints, among which is Acupuncture.

It may not be uninteresting to our readers, to give an account of the various affections in which they employed it, a description of the instrument, and the mode of using it.

"The needle is made long, slender, sharp, of gold, or at least silver, with a wreathed handle.

"It is to be conveyed either by the hand or a little mallet into the part gently, a finger's breadth or more, as the case requires, and to be held there the space of 30 breathings, (if the patient can bear it,) otherwise repeated punctures are rather used. The puncture must be when the party is fasting; deeper in a great than less disease; in old than young men; in grown persons, than in those that are lean and slender; in fleshy parts, than in nervous. The needle is chiefly used in diseases of the head and lower belly, and is applied to the head in head aches, lethargies, convulsions, epilepsy, diseases of the eye, &c. The womb itself may be perforated, (*the Japanese affirm*) and the fœtus wounded, when its motions are enormous, and threaten abortion. In these cases the needle must be applied, whence the distemper arises; to the stronger on the back, to the weaker on the abdomen. When the pulse scarce is perceived, the puncture must be made in the arteries, a little besides the veins. The surgeons keep by them images, wherein all the places in the body proper for the needle, are designed by marks. The author himself was an eye-witness of the use of this puncture on a souldier, who, being afflicted with violent disorders of stomach, and frequent vomitings at sea, suddenly relieved himself by pricking a thumb's-breadth deep into four different places about the region of his *pilorus*."

*Copy of a Letter to Mr. Methuen, from his Gardener.*

"Honoured Sir,—My wif an I have taken the Ian from Winsor. Jenny Cedar has lost her head, the rest of the scrubs are all well. The Oxen are com down to prase the Gods.

From your  
humble servant," &c.

What he meant to say was :

Honoured Sir,—My wife and I have taken the influenza. The Virginia cedar has lost its head : the rest of the shrubs are all well. The auctioneer came down to appraise the goods.

## THE GENERAL MEDICAL COUNCIL: ELECTION OF DIRECT REPRESENTATIVES, 1901.

FELLOW PRACTITIONERS OF ENGLAND AND WALES,—You are perhaps aware from announcements in the medical journals that I have been forbidden at what seems a most inopportune moment by my medical advisers to take part in public meetings. They do not go so far as to advise me to abandon my candidature, but they counsel some diminution of work. I am in the enjoyment of my usual health and my eye is almost itself again. Still I am bound to respect advice given me by my truest friends, whose names would command the respect of the profession.

The relinquishment of practice would be distasteful to me and altogether beyond the necessities of the case. The only other way in which I can relieve myself of work is by retiring from my candidature for the honourable office of representing you in the General Medical Council. I can do so now without putting the Council to the inconvenience and expense of a separate election.

These circumstances determine me to withdraw from the present contest. I cannot tell you with what reluctance I do so, especially at a moment when questions of great interest to the public and the profession are before the Council, in which I have, as I believe, taken a part representing the general judgment of my fellow practitioners.

Nor can I say how grateful I feel to the profession for its kindness and confidence during the last 15 years and of the continuance of which I have ample testimony on the present occasion. I ask you to accept my best thanks.

The office of a Direct Representative in the General Medical Council, with a constituency of over 23,000, is not an easy one. Many questions present themselves at the Council Board in a very different light from that in which they appear when viewed from a purely professional standpoint. And the Direct Representative has to act accordingly. I ask you to believe that on all such questions I have tried to remember the interests of the profession as well as those of the public, and to harmonise the two.

I have endeavoured to advance medical education, to maintain the standards of professional conduct and to keep the Register pure. That I have erred often goes without saying, but I am sure you will be more blind than critical towards my faults and will give me credit for having tried to maintain the cause of Direct Representation in the General Medical Council, which, after all, even its critics must admit, is the great council of the profession.

With deepest thanks,

I am, Fellow Practitioners, your obedient servant.

25, Highbury-place, N.

JAMES GREY GLOVER.

### MEETING AT MANCHESTER.

A meeting of the medical profession was held at the Palatine Hotel, Manchester, on Oct. 31st, under the auspices of the Medical Guild of Manchester and the Medico-Ethical Society of Manchester.

The CHAIRMAN (Mr. Walter Whitehead) explained that the meeting was called to hear addresses from Dr. S. Woodcock of Manchester and Mr. Victor Horsley on subjects connected with the forthcoming election to the General Medical Council.

Dr. Woodcock said that he would most efficiently discharge his function if he addressed himself mainly to the consideration of one question which had great interest, which had excited a good deal of feeling in the profession, and which, notwithstanding that they had been considering it for so many years, still remained an unsolved problem. He referred, of course, to the midwives question. He must ask their patience while he attempted to explain what his conduct on this question had been and what his attitude was towards it. He went back only to the time of their meeting in Manchester when the opposing forces were ranged in ranks on both sides, when they had a battle royal, and when those of them who were opposed to the legislation promoted by the Midwives Committee certainly won a battle. After that they knew that a good deal had to be done and they in the Lancashire and Cheshire Branch appointed a committee with representatives on both sides of the question and they addressed themselves to drafting a measure which they thought might be generally acceptable. The Lancashire and Cheshire Branch did what it could and the report was accepted by the branch, though he was bound to admit with a minority. The report was introduced later to the Central Council in London and his visits to London had convinced him of the absolute necessity of having some alternative plan to that proposed by the Midwives Registration Committee. Mr. Asland, who was then in the Liberal Cabinet, at that time in power, told him that it was no good just to stand up and say that the medical profession would not have this or that legislation, but they must have an alternative scheme ready to propose because the promoters of the Midwives Bill had secured the ear of an influential portion of the House of Commons, they were supported by people in the very highest social position, and

unless there was an alternative scheme submitted he (Mr. Acland) was afraid that the measure would pass. Further, when he (Dr. Woodcock) arrived at the Central Council in London and began to deal with that question in the Parliamentary Bills Committee he found that Mr. Ernest Hart had exactly the same opinion as that expressed by Mr. Acland. It happened that a sub-committee to consider the amendment of the Medical Acts had just been appointed with Mr. Horsley as chairman, and he (Dr. Woodcock) and Dr. Ritchie from Manchester were members, with Mr. George Brown also. The Parliamentary Bills Committee requested that the committee which had been appointed to consider the reform of the Medical Acts should take into consideration this midwives question and they were asked to draft a Bill which they thought would be acceptable to the profession. They tackled that question and sat many times and paid a good deal of attention to the subject and they thought they were engaged in drafting a measure which would be acceptable to the profession and at the same time safeguard the interests and lives of parturient women in the country. The committee framed rules and called the women who should be registered not "midwives" but "midwifery nurses." The alteration to call them "midwives" was not in any sense their work—that was done for them when the draft left their hands. It was done in the Central Council in London. He opposed that alteration to the utmost. They made it clear that the function of the midwifery nurses should be strictly limited and that they should have imposed upon them nursing duties. The committee went further—they added an appendix which laid down distinctly the conditions under which these women would be obliged to call in medical aid. They also took into consideration that there was a danger from what were called lying-in homes. Dr. Woodcock explained the particular class of lying-in home that was referred to and said that they held that those institutions had better be brought under inspection. They framed a measure which they thought would not be objected to by the great bulk of the profession. They were told, however, that in that measure they had violated the spirit and the letter of the Medical Acts. If they had done so they had done it unintentionally; they had no idea of doing such a thing, but if that allegation was true they would have to try again, they would have to make an attempt which should be more satisfactory. But all Dr. Woodcock had to say in regard to that measure was that he felt as a mere act of loyalty to his chairman and colleagues that he was bound to support the result of their labours. He must either do that or disregard his principles and immediately trim his sails to catch the passing breeze. While supporting that measure he did not thereby infer that it was perfect. It was possible that some alternative scheme might be better and prove a better safeguard for the interests of the profession and the public, but hitherto he had not seen an alternative scheme which had altogether commended itself to his judgment. There was a scheme which was drafted, as he thought, by Dr. Bedford Fenwick and his medical friends; at any rate, it had the support of a paper called the *Medical Times and Hospital Gazette*, in which he believed at that time Dr. Bedford Fenwick and Mr. George Brown were interested. From that paper he took the following remarks. Writing in praise of their scheme there was this remarkable sentence: "It appears to us that the consequence would be that many medical men would gladly employ nurses so efficiently trained for attendance upon their poor and parish patients knowing that such parturient women would therefore receive every care and attention and that in the event of any abnormality showing itself medical assistance would be immediately summoned." They would see (Dr. Woodcock continued) that according to Dr. Bedford Fenwick and Mr. George Brown any abnormality was to be diagnosed by the nurse. It was the nurse who was to determine when the medical man was to be called in. That appeared to him (Dr. Woodcock) to be the reintroduction of the unqualified assistant in petticoats. He did not think that it was a scheme which was likely to commend itself to the judgment of the profession. Recently they had had the outline of another scheme which was called the Medical Guild scheme. There had been a little discussion as to the paternity of that measure in the press. He did not know himself that it was quite a new-born child. He thought that it was a sort of foundling adopted by the Medical Guild and it did not appear that it was got rid of by its real parent with the idea of avoiding responsibility, but he was generously hiding himself that when the child was more developed he would be able to augment the resources of its foster parent. This scheme was called "Scheme for the Protection of Parturient Women and their Offspring." It must be understood that any criticism of his was not in an unfriendly spirit. He might say that if any of them had had any experience in drafting Bills they would know that there was a little difference between suggesting outlines and drafting the clauses which might meet with some sort of acceptance by Parliament. He thought that the scheme contained very humane and on the whole very necessary suggestions in the interests of the poor people. As far as the profession went it was a perfectly ideal scheme and he would be glad to see, if that were possible, this ideal realised. The following was the preamble of the Medical Guild scheme: "That in view of the fact that a large share of the mortality and morbidity amongst the parturient women and the newly born of the poorer classes is undoubtedly due to their being attended by ignorant and untrained women, and their not having the services of fully-qualified medical practitioners, the guild is of opinion that legislation is urgently required with the sole object of putting within the reach of the poorer classes the assistance both of a trained nurse and of a qualified medical practitioner, and recommends the adoption of the following scheme as a basis for future legislation." The scheme itself was thus described: "1. That all obstetric nurses be adequately trained in hospital, examined, and registered." They would, he believed, all agree in regard to that. The next point was: "2. That the guardians of the local sanitary authority be the authority for the local administration of the scheme." There could, he said, be no objection to that. The scheme continued: "3. That the local authority shall engage one or more registered obstetric nurses, at such salary as may be practicable, whose services shall be placed, free of all charge to the patient, at the disposal of any woman living in the district, and whose circumstances shall justify it, to nurse her during her confinement and during the puerperal period." He thought that that was a very desirable provision. The next clause was: "4. That each local authority should issue to each nurse a note requisitioning the services of a registered medical practitioner. This note must be taken or sent by the woman to such practitioner as she may select who is willing to undertake this work." He did not think that the woman should have such an option. He thought the patient should have the option.

A short discussion followed in regard to what person the scheme meant to choose to whom to take the note, and Dr. Woodcock continuing said that the scheme did not say what it meant and they must take care in drafting a Bill that it was made clear as to who was referred to. Clause 4 ended as follows: "The acceptance by him of a note shall constitute an engagement on his part to render to her such assistance in her confinement as the nature of the case may demand." "5. That the notes which the practitioner received from the patients shall be redeemed by the local authority at such a rate as may be hereafter fixed. 6. That the question of the suitability of applicants be left to the local authority." He had only to say that that course meant some increase of taxation; it meant the assent of Parliament to a scheme which would involve some considerable amount of expenditure on the part of the local authority. Whether the time was quite propitious for approaching the Chancellor of the Exchequer he was not sure, but he did not wish to say that that was an insuperable difficulty. The Medical Guild was only a local organisation and could not expect to have the sort of influence which might be exercised by a larger and greater national or imperial organisation. He might say with regard to that scheme that if their own scheme failed to satisfy what appeared to be the demands of the profession, and in consequence of his having no confidence in the scheme which he had previously mentioned for the registration of nurses and seeing the difficulties in it that he did, he was prepared in regard to the guild scheme, if it were sent to the British Medical Association, which was the organisation through which they would have to work in the future to exert pressure on Parliament and on the public, to give it his most earnest attention. Under the present conditions they could not make any great impression, but if that scheme were sent to the representative meeting proposed for the Association, and if that meeting appointed a committee to deal with the matter, he was confident that it would be possible to draw up a Bill on those lines and he would give it all the support that was in his power, and he would do what he could to arrive at a satisfactory conclusion of that question which had been agitating the profession for so many years. He had no idea in the world of interfering with or violating the spirit of the Medical Act in any way. He would like to see midwifery practice entirely under the control of medical practitioners, and he thought that by-and-by they would have an Amazonian contingent in the medical profession which would satisfy the sentimental qualms of those who considered that women should be attended by those of their own sex. When he said that he was prepared to abandon the former scheme, which he was not absolutely wedded to, it was not his scheme any more than it was Mr. Brown's or Mr. Horsley's scheme, both of whom were members of the committee, and he did not remember that Mr. Brown ever protested against the report being on the lines that they were proceeding on: if they had failed in that direction let them all work together and let them have another try. The time had, however, arrived when they should cease internecine warfare and they should be able to present a united front to their opponents. He thought that he had been explicit in explaining his position. He did not speak of the conduct which he had pursued in an apologetic manner; he had explained the circumstances which led him step by step in the course he had followed. If they had succeeded in arriving at what might not be considered a satisfactory solution, then let them hark back and have another try. In conclusion Dr. Woodcock said that they would have to use the reconstituted British Medical Association in the way that people did use instruments to effect necessary results.

Mr. VICTOR HORSLEY said that in regard to the midwifery question, although it had never found full public support or adequate reference in the medical journals, there was before the medical profession a distinct series of points to which the General Medical Council had given their authority. Those points were contained in the public minutes of the General Medical Council and they embodied the principles upon which all safe legislation should be founded. His opinions on the matter were therefore in print both in regard to the safety of the public and the interests of the profession. With especial reference to what Dr. Woodcock had said he would add that he was five years ago chairman to a sub-committee for drafting the Midwifery Nurses' Bill, a sub-committee of the Parliamentary Bills Committee. They drafted the Bill mentioned by Dr. Woodcock, but he would like to remark that that Bill was circulated to the branches of the British Medical Association and was confirmed by the branches. There was no question whatever that the Association as such was pledged to legislation of some kind. It was no final legislation that was proposed, it was a draft Bill, as Dr. Woodcock said, and he (Mr. Horsley) wished to endorse entirely those opinions. If other schemes were brought forward which were better let them act on that which they thought was the best. Manchester was the place chosen for the great meeting of the Association next year and that meeting ought to be the record meeting of the Association for the reason that the representative meeting of the Association would be inaugurated there in the following July and that representative meeting would be the first occasion on which the views of the very different classes of practitioners throughout the country could be heard in a combined manner, provided, of course—and he thought it was perfectly possible—that the by-laws and articles of association were passed at the two statutory meetings which had to be held. For his part he would not accept anything as the voice of the profession on the midwifery question until it had found expression in a resolution of a really representative meeting. He assured them that when the sub-committee of which he was chairman invited criticisms from the branches, although they got favourable answers from a majority of the branches the criticisms received were, to say the least of it, not very strong. He was quite sure that was simply because they had no means of directly hearing the opinions of men representing the profession in different parts of the country. He hoped that they would understand clearly that all the legislation which had been drafted in the Association had been drafted for the purpose of counteracting the midwifery legislation introduced into the House of Commons which they all disagreed with. There was reason to believe that at the next meeting of the British Medical Association they would obtain the real views of the profession in this matter. At Cheltenham he observed that the scheme that Dr. Woodcock had referred to as emanating from Manchester was one which must commend itself to everyone who had taken an interest in the subject. Now, as regards what had passed in the Council since they elected him he was not going to inflict upon them the history of all that had occurred, which was contained more or less perfectly in the medical journals, but he wished to allude to one or two points. The

first and most fundamental point was this, that again they must use every effort to come to the statutory meeting in London to comment upon and pass the necessary articles and by-laws to carry out the scheme adopted at Cheltenham to reform the British Medical Association. His experience of the work in the Council showed him that they might ask for more Direct Representatives and they might get them, but that of itself would not reform the Council. In fact, they were entitled under the Act to only one more Direct Representative. What was one more vote? What was six instead of five, with 25 against them? There was only one way of getting at the root of the evil and that was to have an absolutely new Medical Act. It had been suggested repeatedly that if the General Medical Council was opposed to any new Medical Act that it was folly to think that any Government would favour reform. He did not believe it. He had endeavoured to state what was the relation of the Government to the General Medical Council. The Government at the present moment regarded the General Medical Council with absolute contempt and indifference, and he had pointed out in his reports to his constituents that the Privy Council had betrayed the General Medical Council on two great questions—the midwifery question and the question of practice in this country and Italy, the so-called reciprocity question. To say that the Government would not bring in a Medical Act to reform the General Medical Council if the General Medical Council opposed such a Bill was, he thought, ridiculous. The Government would support any Bill if they thought that the medical profession as a whole was going to move against them, and that was what they ought to seek to persuade the Government to think would take place if they failed to help them in the new Medical Bill. He did not believe that it would be necessary to use any threats at all nor would it be necessary with the new Association to work it on such lines because he thought the desired result could be brought about as a matter of bargain. The principle of bargain was already adopted in the Act of 1858, only it was not carried out. He believed it would be possible to recast the new Medical Act so as to provide a good bargain for them on one side and to provide that the General Medical Council should be really representative of the whole medical profession. It was essential to recognise that they could not get along without the General Medical Council. It was a very useful body when properly organised and if properly directed. The trouble had been that it was not properly worked; it was in the hands of the corporations which were now nothing but mere coteries of a few leading men in the profession, and it did not express the sense of the profession. The Council of the Royal College of Surgeons of England was composed of gentlemen in every sense of the word, but men who had arrogated to themselves the rights of all the members of the Corporation, and that was a position which he felt was an extraordinary position for the leaders of their profession to assume. But such as it was it was taken and they, with the other corporations in the General Medical Council, thought only of the interests of the corporations and not of the profession. Therefore they must have a new Medical Act and if they returned him in the following year again to represent them in the General Medical Council he would work there as he had done in the past from that point of view. But as he had said before they must not labour under any delusion, the General Medical Council was not the body that could or wished to carry out what they wanted in this work of progress and reform. He wished to speak a word with regard to the present election and in so doing he spoke simply as an individual at the meeting, as a member of the profession to which they all belonged. These elections offered a chance of ameliorating their position in the General Medical Council to a certain though perhaps small degree. But it did so from this point of view, that if the practitioners throughout the North of England, where practice was of a different kind to that which they saw in the South of England, would select a man to represent them in the Council, he believed that the result would be that they would have the direct expression of perhaps the strongest branch of the profession and that thereby they would gain power because they would then find that instead of the remarks of a Direct Representative being received with contempt and derision they would be received with respect. It was very easy for them to vote for him and to send him to the Council, but if he rose to speak on some question with which they were all agreed should be determined in a certain direction, and if one of his colleagues got up to support it and was absolutely browbeaten by the President, what did they suppose was the effect on the question? It was simply that its prestige was hopelessly damaged in the minds of many members of the Council who otherwise might have given a fair consideration to the subject. That being the position at the present time he thought to a large extent it was due to the fact that all the three Direct Representatives for England and Wales lived in London. Dr. Glover, Mr. Brown, and he himself were all well known personally to those members who represented the corporate bodies, and they could not get away from personal considerations in this case because such considerations did weigh heavily with the members of the Council and they judged of the merits of the question not only by the details of a measure but by the merits of the person who advocated it. If they returned Dr. Woodcock as representing the North, as representing medical education in the North, and above all as representing the practice of the medical profession in the North, they would have advanced one step, and a very important step, towards the furtherance of their interests in the General Medical Council. Speaking therefore as an independent and disinterested observer in that matter he could not again more strongly urge upon them that Dr. Woodcock's election would create a happy addition to their strength in the General Medical Council.

In reply to Mr. F. B. HARGREAVES Dr. WOODCOCK explained that he was much interested in the question of vaccination, which should be sufficiently and efficiently performed. He did not care who did it, but the Government should lay down some definite rule as to what was efficient vaccination and then let them make contracts with whom they liked. He (Dr. Woodcock) was not in favour of the registration of midwives. He had never thought so; he was in favour of the registration of obstetric or midwifery nurses and to the fullest extent possible he would place them under medical control.

In reply to an inquiry from Mr. R. H. WOLSTENHOLME Dr. WOODCOCK replied that he was perfectly prepared to give a full trial to the scheme at the Medical Guild of Manchester.

In answer to Mr. COLIN CAMPBELL Mr. HORSLEY stated that the question of the legality of councils of the corporations electing representatives for the General Medical Council had been settled by the South London Medical Club who obtained counsel's opinion on this point.

From that it appeared that in the case of the Royal College of Surgeons of England the corporate bodies have such powers in their charters that the courts would only say that the Council of the Corporation was justified in acting as a corporation in a matter such as an election of representatives. It was only by fresh legislation that the profession could procure the restoration of their rights. The universities were in a worse case, and it was notorious that the member of the General Medical Council representing the University of Durham was elected by clergymen, lawyers, and only a sprinkling of medical men.

Mr. WOLSTENHOLME said he was most anxious to support Dr. Woodcock as a local candidate and would do so if Mr. Horsley and he would do their best in the case of midwives being registered to see that they should act as nurses and should do the nursing themselves. He gave details of a midwife in his neighbourhood who did not do any nursing.

Dr. WOODCOCK explained that the British Medical Association Bill had a distinct clause penalising a midwife who employed an unregistered woman to assist her.

Dr. BROWN RITCHIE pointed out that any deputy must be registered. The conversation on this subject was concluded by Mr. HORSLEY who said that the Bill of the Association contained regulations that each of these registered women was to nurse as well as to attend to the labour, and if anything happened that such a woman could not go to a case she had a perfect right to employ another woman who was equally registered as herself to go and do the work for her as a deputy. It was the same thing as themselves, if they could not do a case they sent their assistant or a friend, but they had to send some one who was defined under the same Act of the Legislature, and that was the real point at issue.—In reply to Dr. BROWN RITCHIE, Mr. HORSLEY said they were all agreed that any individual who touted himself for patients after the manner of the medical aid societies would be just as liable to the penal action of the General Medical Council as a man connected with a medical aid society that touted for members.

In answer to a further question by Dr. BROWN RITCHIE Mr. HORSLEY said that the members of the General Medical Council were beginning to recognise that the corporations were of no use for disciplinary purposes and he thought that their responsibility in that respect was in course of recognition by the authorities.

Mr. G. H. BROADBENT inquired of Dr. Woodcock if he would do all that he could to insist in the General Medical Council on the fixing of a wage-limit and also on the Council insisting on friendly societies being under the direct control of the medical staff.

Dr. WOODCOCK replied that he did not suppose the General Medical Council had any control over anyone but registered persons. He was in favour of a wage-limit but he considered that one great conciliation board would not be of much value, especially as the representatives of the friendly societies declined altogether to discuss the question of wage-limit. Local conciliation boards might be instituted, but there ought to be clear understanding on the part of every member of the board that there should be a wage-limit.

Dr. C. MACPHE (Bolton) said he had had a sort of feeling that Dr. Woodcock was not quite in line with their opinions, but his explanation was so clear and explicit that no one would go away without the conviction that he was the man to support.

The usual votes of thanks terminated the proceedings.

#### ANNUAL DINNER OF THE WIGAN AND DISTRICT MEDICAL GUILD.

Mr. Victor Horsley and Dr. S. Woodcock were entertained by the Wigan and District Medical Guild on Oct. 31st on the occasion of the annual dinner of the guild held at the Royal Hotel, Wigan, with Mr. W. MITCHELL ROOCROFT in the chair.

Sir WILLIAM M. BANKS proposed the toast of "The Wigan and District Medical Guild." He said that he would like to explain to Mr. Horsley the way in which the guild worked, and he gave as an example the facts of a case of a certain medical man who came to Wigan and paid a large sum of money for a practice, afterwards marrying and having a family. He had borrowed the money to pay for the practice, and after many a long year he paid it off and then contracted an illness from a patient and died, leaving a widow and three little children. That man was a member of that guild. The members of the guild decided that for 12 months not a single club that that medical man had held should be accepted by any practitioner in the town, and the practice was sold for a good and fair price for the benefit of the widow and children. All the members of that guild played fair with the in-coming medical man and saw to it that the patients of the man who had died were not lost to the practice. Sir William Banks concluded by discussing the two things from which he considered the profession suffered most—namely, the over-pressure of numbers and the utter want of cohesion.

Dr. WOODCOCK also spoke for a short time in support of this toast. Referring to the excellent results obtained by medical men combining together he said that at Oldham so complete was the organisation of the medical men that the friendly societies had to pay ordinary medical fees.

Mr. ROOCROFT, chairman of the Wigan and District Medical Guild, in responding to the toast, said that there were only two medical men in the district who were not in the guild, and one of those was connected with a medical aid association, and one of them, in his opinion, a young and misguided man and a stranger. They pitied him for being a slave and sincerely trusted that it would not be necessary to call in to their assistance those severer measures which might be used if they acted on the resolution passed by the General Medical Council that they disapproved of medical practitioners who associated themselves with medical aid societies that touted for patients.

Mr. LUTHER COOKE proposed the health of "The Guests," which was replied to by Mr. VICTOR HORSLEY.

Mr. HORSLEY said: Mr. Roocroft and gentlemen, I thank you very much for your kind reception of your guests. I may venture to say that I am specially qualified to do so, if Mr. Mayor will allow me to speak on behalf of the non-medical as well as the medical guests, because the General Medical Council on which I have the honour to sit by your favour is a body constituted to protect the interests of the public as well as to watch over the interests and education of the pro-

profession. As a matter of fact, I do not think that the public has any idea of what the functions of the General Medical Council are. That body was constructed by the State in order that the public might recognise who was a properly qualified medical practitioner and who was not. It is quite true the State also agreed that if medical men would duly qualify themselves the State would protect their practice, but I regret to say that the State has not carried out its share of the bargain. The General Medical Council has, however, done an inestimable service to the general public because it is the solitary exception of a professional body that purifies the profession it is connected with. The Incorporated Law Society, if we may trust the papers, might do much more for the lawyers, but the General Medical Council has done up to the present time a great deal in purging the medical profession of evil-doers and in that respect it has done well. In regard to what Sir William Banks has said of the overstocking of the profession a great many of the evils of the medical aid associations did arise from overstocking of the profession, but four or five years ago I showed that the flow into the profession of recruits had begun to diminish steadily, the decrease beginning as long ago as 1895, and from that time until now there has been a steady diminution so that we cannot say at the present moment that overstocking is the cause of medical aid associations. I believe that this medical aid question is partly a socio-political question and partly a financial question on the part of the friendly societies—they want to buy in the cheapest market. The members of the friendly societies cannot recognise the conditions of medical practice, they cannot recognise that under the so-called contract system they are not buying what they think they are buying, they are not getting a fair return for what they consider a legitimate expenditure. In other words, they do not get medical attendance in the proper sense of the word. This brings us to a misunderstanding of the General Medical Council towards medical aid work for many years. They no more understood the question than did the general public. When I entered the Council four years ago it was quite evident that its members did not grasp the conditions under which a medical man connected with a medical aid society carried on his work, because at that time, four years ago, there was no intention on the part of the General Medical Council to take up the attitude which we were delighted to see it adopt in the case of Dr. Irvine. Now the General Medical Council has through a special resolution offered to look upon any case properly brought before it—any specific case—in the same way as it would look on any other instance of unprofessional conduct. And here, again, I think the public do not understand the bearing of what we call unprofessional conduct; they do not understand that medical etiquette is a system calculated to preserve that due respect for the responsibility of life which every medical practitioner takes upon himself when he becomes a qualified medical man. You must have some such system to put that responsibility on to one individual and to keep it there, and it is that sense of responsibility which furnishes that basis of action on the part of this guild which seems to me most pathetic and tragic in its details—I refer, of course, to the case of the sale of the practice in this town arranged for the widow by this guild. I only want to emphasise the fact that from the point of view of the public, as well as from the point of view of the profession, the interests of both are the same. It is our interest to see that the members of our profession do their work honourably; it should be the interests of the public to support us in endeavouring to carry that out. As soon as the public recognise our motives you may be perfectly sure that the public on their side will do their part, and if they only learn that we are working for the safeguarding of the health of the community then they will support the profession in exactly the same way as they have gradually come to do in regard to sanitation. The public gradually learnt that the medical profession in endeavouring to gain sanitary reform was acting honourably in the interests of the public. I believe that it will be the same in regard to friendly society work and that it will be brought about by a better understanding and by meetings of this kind. I do not believe in a conciliation board. I do not believe in artificial means of any kind in which there is not to be a free and clear discussion by both parties. But this guild represents to my mind an ideal condition which would be stronger if it were under another name, and that name I should like to see the "British Medical Association." It is perfectly evident to everyone who studies social politics at all that combination is absolutely essential to progress and, of course, it follows that we must have every member of the profession enter into such combination. You have in the British Medical Association some 18,000 members of the profession, that is our combination. If we could only have this Association divided up into small bodies having real autonomy each of these bodies or divisions in a town—such, for instance, as your guild—would be a division of the British Medical Association, then by each of these bodies sending a representative to an annual meeting you would have the most complete combination of the profession at one blow. This is what we hope to see carried out in the next session by the adoption of the by-laws and regulations of the British Medical Association. I hope that some of you may find it possible to come to London to the statutory meetings and support the scheme to remodel the Association by passing the new articles and by-laws; I hope from the bottom of my heart that you will send Dr. Woodcock to the Council; and I intend, when my seat at the Council becomes vacant, to ask you to send me there for another term; and I believe that at the end of that period we shall find ourselves not only working with a reformed British Medical Association but also under the influence of a new Medical Act.

Dr. W. CARTER (Liverpool) proposed "The Town and Trade of Wigan," which was responded to by Mr. T. FYANS, the mayor, and by Mr. W. BERRY, chairman of the Wigan Infirmary.

**CHARING CROSS HOSPITAL.**—The Council have decided to add an ophthalmic department to this hospital. The days and time of attendance for patients will be on Wednesdays and Saturdays at 9 A.M.

**LITERARY INTELLIGENCE.**—MESSRS. W. B. Saunders and Co. have in the press for early publication during the autumn "Anatomy in Relation to Art," in one quarto volume, and "Regional Anatomy," fourth edition, in two volumes. Professor George McClellan, professor of anatomy, Pennsylvania Academy of Arts, is the author of both works.

## ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia was held on Oct. 31st, Sir WILLIAM SELBY CHURCH, Bart., the President, being in the chair.

The following gentlemen having passed the required examination were admitted as Members of the College:—Robert Hamilton Bell, M.A., M.B. Cantab., L.R.C.P. Lond.; Leonard Stanley Dudgeon, L.R.C.P. Lond.; Charles Henry Fennell, B.A., M.B. Oxon., L.R.C.P. Lond.; David Nunes Nabarro, M.D., L.R.C.P. Lond.; Frank Charles Shruballs, M.A., M.B. Cantab., L.R.C.P. Lond.; William Mitchell Stevens, M.D., L.R.C.P. Lond.; Septimus Sunderland, M.D. Brux., L.R.C.P. Lond.; and Eustace Talbot, M.A., M.B. Cantab., L.R.C.P. Lond.

Licences to practise medicine were granted to 106 gentlemen who had passed the required examinations.

The following communications were received:—

1. From the Lord President of the Council forwarding a letter from the Egyptian Government announcing that a Congress of Medicine will be held in Cairo in December, 1902, and inviting the College to send delegates.—It was decided to send a delegate to the Congress on the nomination of the President.

2. From the President of the Fourteenth International Congress on Medicine to be held at Madrid in April, 1903, inviting the College to take part in the same, and inclosing copies of the Regulations.—The invitation was accepted.

3. From the executors of the late Dr. John Cavafy announcing his bequest of £500 to the endowment fund of the College.—The PRESIDENT proposed that a formal vote of thanks should be forwarded to the executors and other members of the family for the handsome gift.—This was carried unanimously.

4. From Dr. Norman Moore, conveying a proposal from Mrs. Fitzpatrick to found a lectureship at the College on the History of Medicine in memory of her late husband, a Member of the College, and inclosing a draft for £2000.—On the proposition of Dr. NORMAN MOORE, seconded by Dr. J. F. PAYNE, a cordial vote of thanks was accorded by the College to Mrs. Fitzpatrick for her munificent gift which was gratefully accepted.

5. From Mr. S. Cowell, reporting certain proceedings of the Council of the Royal College of Surgeons of England.

The audited accounts for the year ending Sept. 29th last were laid before the College and the quarterly report of the Finance Committee was received.

A report was received from Dr. C. Theodore Williams, the delegate of the College at the recent Congress on Tuberculosis, and another report was received from Sir Felix Semon who was appointed to convey the congratulations of the College to Professor Virchow on his eightieth birthday.

A report was received from the Committee of Management stating that two schools had been omitted from the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, practical chemistry, and biology, and that Blaenau Festiniog County School and Southend Technical School had been added to the list. Dr. Frederick Taylor was re-elected a member of the Committee of Management and Dr. P. H. Pye-Smith was re-elected a member of the Laboratories Committee.

Reports were received from the Laboratories Committee and from the Examiners for the Licence.

A list of books presented to the library during the past quarter was received and the thanks of the College were accorded to the donors.

The REGISTRAR, in accordance with a resolution of the College of July 25th last, moved that by-law lxvi. be amended by the addition of the words in italics in the copy below, and re-enacted for the first time as follows:

The Council shall consist of the President, censors, and treasurer of the College, of the representative of the College in the General Council of Medical Education, of one of the representatives of the College on the Senate of the University of London, and of 12 other Fellows of the College.

Also that the following regulation should be appended to the by-law:

*Each University representative shall serve alternately as a Member of Council for a term of two years, or for such shorter term as he may remain a representative.*

The PRESIDENT then dissolved the Comitia.

## Public Health and Poor Law.

### LOCAL GOVERNMENT BOARD.

#### ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

*City of London.*—The condition *quod* revaccination of the resident population of the City is not eminently satisfactory, at least in so far as the information in the hands of the medical officer of health is concerned. According to this only four adults were revaccinated during the year 1900. It is not clear, however, how the information with regard to revaccination is procured, and doubtless a large number of persons undergo the operation unknown to the authorities. Dr. W. Sedgwick Saunders, the late medical officer of health, advised that no unvaccinated child should be admitted into the artisans' dwellings, and Dr. W. Collingridge practically endorses the recommendation. The City forms a very important distributing centre for certain foods and as such it is of interest to the consumer to know that 312 loads of vegetables, condensed milk, fish, tinned meat, &c., were removed at the request of the owners during 1900. We note, too, that a large quantity of unwholesome fruit consigned to jam manufacturers in this country was destroyed. As many as 410,380 tons of meat were delivered at the Corporation Markets, Smithfield, during the year now under review, and of this amount some 962 tons were seized by the inspectors. The proportion of "country" and "town" killed meat delivered is gradually decreasing, while that of "foreign" American and Australian meat is steadily increasing. The condemned meat is apparently disposed of to a firm of contractors who, during 1900, paid £2525 3s. for it. It seems that the meat is treated in some fashion—perhaps with picric acid—before being disposed of, but it would be instructive to know the ultimate destiny of such meat. At Billingsgate Market 187,684 tons of fish were received, the bulk of which was land-borne. Of this total nearly 770 tons were condemned.

*Southampton Urban and Port District.*—The census population of Southampton was 104,911, figures which showed that the estimates had been somewhat in excess. As regards small-pox there were 21 cases isolated during the year, several of them having been removed direct from mail-steamer arrivals in the port, and the hospital ship seems to have performed good service in the matter of isolation. Mr. A. Wellesley Harris, the late medical officer of health, but the author of the report under notice, advocates the inclusion of small-pox in the provisions of the "plague order." Were this the case local authorities to whose districts persons from small-pox infected ships are travelling could be informed of their arrival. The new isolation hospital was opened during 1900, and already the neighbouring authorities have made use of this provision for cases of infectious diseases occurring in their districts. The charge for such patients for the public wards is one and a half guineas a week, and for the private wards three guineas, but the charges vary somewhat according to the nature of the disease. The provision of private wards will be very acceptable to persons able to pay for them, albeit this practice may lead to some unpleasant distinctions at times. The annual report as to the work in this part of Southampton shows what a serious responsibility has devolved upon the medical officer of health in consequence of the large transport traffic passing to and fro between South Africa and Southampton. Mr. Harris reports that about 45,000 troops were brought to the port during 1900, and amongst them were many suffering from enteric fever. The isolation provision at Southampton seems to be now very complete, and arrangements have been made with the War Office for the provision of special contact camps for troops under observation. The good work which has been done at Southampton is very largely due to the efforts of Mr. Wellesley Harris who is to be cordially congratulated upon his promotion to a metropolitan borough.

*Borough of Hackney.*—Dr. J. King Warry draws attention in his current annual report to the difficulty which the modern "flat" presents in the direction of the satisfactory disposal of house refuse, and it is a difficulty with which most dwellers in "flats" have been brought inconveniently into contact. Some of Dr. Warry's remarks apply more particularly to the tenements of the poorer

classes, but they are not without application to the highly-rented "flats" of the well-to-do. The storage of house refuse for a week in the scullery, however "sanitary" the dustbin may be, is open to the strongest objection and is more to be condemned than the shoot which has an opening into the staircase or passage in connexion with each floor. But perhaps the most objectionable of all is when the shoot opens directly into the scullery or kitchen and is only separated therefrom by a door which is supposed to be, but rarely is, air-tight. When the shoot is being used by other occupants of the block a cloud of highly offensive dust is apt to force its way through the interstices of the door to the great inconvenience of the occupants of the room and to the serious pollution of articles of food. The erection of such devices as these should no longer be allowed.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7003 births and 3859 deaths were registered during the week ending Nov. 2nd. The annual rate of mortality in these towns, which had been 15.9, 16.8, and 16.7 per 1000 in the three preceding weeks, rose again last week to 17.6 per 1000. In London the death-rate was equal to 17.4 per 1000, while it averaged 17.7 in the 32 large provincial towns. The lowest death-rates in these towns were 8.1 in Croydon, 10.5 in Swansea, 11.0 in Cardiff, and 11.5 in Leicester; and the highest rates were 21.5 in Liverpool and in Newcastle, 22.0 in Burnley, 22.1 in Preston and in Salford, and 23.7 in Blackburn. The 3859 deaths in these towns included 371 which were referred to the principal zymotic diseases, against 488, 468, and 398 in the three preceding weeks; of these 371 deaths 88 resulted from diarrhoea, 71 from diphtheria, 65 from measles, 59 from "fever" (principally enteric), 46 from scarlet fever, 35 from whooping-cough, and seven from small-pox. No death from any of these diseases occurred last week in Croydon; in the other towns they caused the lowest death-rates in Brighton, Cardiff, Nottingham, Derby, and Oldham, and the highest rates in West Ham, Blackburn, Sheffield, and Sunderland. The greatest mortality from measles was recorded in Norwich, Blackburn, Huddersfield, Halifax, and Sheffield; from whooping-cough in Sunderland; from "fever" in Salford and Halifax; and from diarrhoea in West Ham, Burnley, Preston, Huddersfield, and Sunderland. The mortality from scarlet fever showed no marked excess in any of the large towns. The 71 deaths from diphtheria included 36 in London, six in Liverpool, four in West Ham, four in Sheffield, and three in Bristol. Six fatal cases of small-pox were registered in London and one in Plymouth, but not one in any other of the 33 large towns. There were 284 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, Nov. 2nd, against 175, 172, and 180 on the three preceding Saturdays; 169 new cases were admitted during the week, against 37, 47, and 57 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had increased from 2994 to 3353 at the end of the eight preceding weeks, had further risen to 3391 on Saturday last; 425 new cases were admitted during the week, against 422, 404, and 400 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 186, 196, and 242 in the three preceding weeks, further increased last week to 327, but were 24 below the corrected average. The causes of 39, or 1.0 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Salford, Bradford, Leeds, Hull, and 10 other smaller towns; the largest proportions of uncertified deaths were registered in Nottingham, Liverpool, Sunderland, and Newcastle.

##### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had risen from 14.5 to 19.3 per 1000 in the four preceding weeks, further increased to 19.9 per 1000 during the week ending Nov. 2nd, and was 2.3 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14.4 in Paisley and 14.5 in Greenock to 22.1 in Leith and 22.2 in Dundee. The 634 deaths in these towns included 32

which resulted from diarrhoea, 14 from measles, 14 from "fever" (including one from bubonic plague), nine from diphtheria, five from scarlet fever, and five from whooping-cough. In all, 79 deaths were referred to these principal zymotic diseases last week, against 79 and 69 in the two preceding weeks. These 79 deaths were equal to an annual rate of 2.4 per 1000, which was 0.7 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhoea, which had been 32, 30, and 27 in the three preceding weeks, rose again last week to 32, of which 15 occurred in Glasgow, five in Dundee, and four in Aberdeen. The deaths from measles, which had been 15 and 12 in the two preceding weeks, rose again to 14 last week, and included 13 in Glasgow. The fatal cases of "fever," which had been six, five, and 13 in the three preceding weeks, further increased last week to 14, of which 10 (including the death from bubonic plague) were registered in Glasgow, two in Edinburgh, and two in Paisley. The deaths from diphtheria, which had been 12 and five in the two preceding weeks, rose again to nine last week and included four in Glasgow and three in Edinburgh. The fatal cases of scarlet fever, which had been seven, five, and four in the three preceding weeks, increased last week to five, of which four occurred in Glasgow. The five deaths from whooping-cough showed a decline from recent weekly numbers and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 75, 97, and 133 in the three preceding weeks, were again 133 last week, and were 15 below the number in the corresponding period of last year. The causes of 27, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19.7, 19.9, and 19.3 per 1000 in the three preceding weeks, rose again to 22.7 per 1000 during the week ending Nov. 2nd. During the past four weeks the death-rate has averaged 20.2 per 1000, the rates during the same period being 16.1 in London and 16.0 in Edinburgh. The 163 deaths of persons belonging to Dublin registered during the week under notice included 19 which were referred to the principal zymotic diseases, against 21, 10, and nine in the three preceding weeks; of these, nine resulted from diarrhoea, five from "fever," four from whooping-cough, and one from scarlet fever. These 19 deaths were equal to an annual rate of 2.6 per 1000, the zymotic death-rate during the same period being 1.5 in London and 1.3 in Edinburgh. The fatal cases of diarrhoea, which had been 14, five, and four in the three preceding weeks, rose again last week to five. The deaths referred to different forms of "fever," which had been eight, six, three, and 0 in the four preceding weeks, increased to five last week. The mortality from whooping-cough exceeded that recorded in any recent week. The 163 deaths in Dublin last week included 42 of children under one year of age and 42 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a marked increase over the respective numbers in the preceding week. Eight inquest cases and eight deaths from violence were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of eight, or nearly 5 per cent., of the deaths in Dublin last week were not certified.

### THE SERVICES.

#### ROYAL NAVY MEDICAL SERVICE.

ON the occasion of the return of their Royal Highnesses the Duke and Duchess of Cornwall and York in H.M.S. *Ophir* from the Royal visit to the colonies Surgeon Robert Hill has been promoted to Staff Surgeon in His Majesty's Fleet.

The following appointments are notified:—Staff Surgeon J. Hughes to the *Amphitrite*. Surgeons: C. S. Bennetts to the *Fearless*; W. W. Keir to the *Lion*; W. H. Pope, to the *Rinaldo*; G. Ross to the *Juno*; S. T. Reid to the *Vestal*; G. M. Eastment to the *Gleaner*; and J. C. Rowan to the *Mutine*. Civil Practitioner A. H. S. Todd, to be Surgeon and Agent at Kingstown and Dalkey.

#### ROYAL ARMY MEDICAL CORPS.

Surgeon-General A. F. Preston, Director-General, Army

Medical Service (temporarily), to be an Honorary Physician to the King, vice Surgeon-Major-General W. A. Thomson, retired pay, deceased. Dated Nov. 2nd, 1901.

Major C. C. Reilly has arrived at Dover and has been posted to the Station Hospital, Western Heights, for duty. Captain G. A. Moore has left Shorncliffe for service in South Africa. Lieutenant A. J. Williamson proceeds from Lincoln to York for duty. Surgeon-Lieutenant K. N. Taylor, Army Medical Reserve (3rd Volunteer Battalion the Essex Regiment), assumes the duties of Assistant to the Medical Officer in charge of officers, women, and children, Colchester.

Captain R. E. G. Phillips is seconded for service with the South African Constabulary. Dated March 17th, 1901. Lieutenant-Colonel H. J. McLaughlin retires on retired pay. Dated Nov. 6th, 1901.

#### MILITIA MEDICAL STAFF CORPS.

Montague Adye Cholmeley to be Surgeon-Lieutenant.

#### VOLUNTEER CORPS.

*Artillery*: 2nd Devonshire (Western Division, Royal Garrison Artillery): Surgeon-Lieutenant L. L. Hanham to be Surgeon-Captain. *Royal Engineers*: 1st Newcastle-on-Tyne: Surgeon-Lieutenant-Colonel R. F. Cook retires under paragraph 111 Volunteer Regulations, with permission to retain his rank and to wear the uniform of the corps on retirement. Dated Nov. 2nd, 1901.

#### VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Captain H. D. Mason, Royal Army Medical Corps, to be Adjutant on increase of Establishment.

#### SOUTH AFRICAN WAR NOTES.

Civil Surgeon W. M. Mackay left Cape Town for England on Oct. 24th.

Captain D. D. Shanahan, R.A.M.C., received a gunshot wound in the right hip at the action near Vleifontein on Oct. 24th.

#### ARMY ADMINISTRATION.

A new Order in Council has been published in the *London Gazette* of Nov. 5th defining the duties of the principal officers who, under the Secretary of State for War, are charged with the administration of the departments of the army. Speaking broadly, the duties and position of the principal heads of departments, as it seems to us, remain much the same as before, subject, however, to their being more or less modified according as they happen to come under the terms of the new Order under the direct control or simply under the supervision of the Commander-in-Chief. In the case of the Adjutant-General's department, for instance, it is under the control of the Commander-in-Chief, while in that of the Director-General of the Army Medical Department the word "supervision" is used to define the Commander-in-Chief's relation to the head of that service. It will be seen, however—and this the great point—that the Director-General is to advise the Secretary of State on all matters connected with his department. We make the following extract from the Order in question:—

"*Department of the Director-General, Army Medical Department.*—The Director-General, Army Medical Department, shall, under the supervision of the Commander-in-Chief, be charged with the administration of the medical establishments of the army and of the Royal Army Medical Corps, with dealing with sanitary questions relating to the army, with the preparation of medical and sanitary statistical returns, and with the supply of medical stores to the army. He shall advise the Secretary of State as to the general distribution of the Royal Army Medical Corps, as to the appointment of officers to, or their removal from, responsible positions therein, and on all other matters connected with his department. He shall make such inspections as may be necessary to ensure the efficiency of the services under his control, and shall submit proposals for the annual estimates for the medical services."

#### THE WAR IN SOUTH AFRICA.

The War Office on Nov. 5th issued its usual table showing the casualties in the field force in South Africa reported during the month of October and the total casualties reported from the beginning of the war up to and including that month. From this we gather that the reduction of the military forces through war in South Africa—from deaths, missing, and prisoners, and invalids discharged as unfit for

further service—amounts to a total of 22,773 officers, non-commissioned officers, and men.

#### HOSPITAL ORDERLIES FOR THE ROYAL ARMY MEDICAL CORPS.

The Director-General, Army Medical Service, has intimated that hospital orderlies are still sorely needed for service in South Africa, and that the immediate assistance of the St. John Ambulance Brigade to the extent of 200 men would be very highly valued.

"Audi alteram partem."

### THE DANGERS OF A COMMON COLD.

To the Editors of THE LANCET.

SIRS,—I feel sure we are all pleased to see in our public places, cars, &c., notices prohibiting spitting. Whether we Englishmen are more prone to that form of dirtiness and bad taste than our American cousins and foreign friends I am doubtful. The upper few inches of the earth's living mould is the natural and proper receptacle of all animal and human excreta. Its deposition at a sufficient distance from habitation is neither poisonous to its surroundings nor offensive to the most delicate taste. That we must expectorate under many conditions too numerous to mention and at most inconvenient times and places is not sufficiently remembered by our sanitary legislators. The use of soft paper handkerchiefs ought largely to be encouraged as being much preferable to linen: eventually they should find their way to that resolver and perfect cleanser of all dirt, the fire. It is quite possible that at some future time all municipal authorities will provide in certain situations receptacles for the holding of used handkerchiefs until their removal by the corporation. The association of man with his fellows bristles with difficulties and dangers. I should like to instance particularly the infectiousness of common colds. Whether these colds, catarrhs, influenzas (?), and febriculas are produced by a chill or are one of the many manifestations of the growth of specific and distinct *materia morbi* is a question awaiting the patient investigations of the bacteriologist. That colds are personally infectious is an accepted axiom by many of the intelligent laity, and I know many people with delicate chests who do not fear exposure to inclement weather, but who, from personal experience, have a righteous dread of coming near anyone suffering from a cold. The opinion of our profession on this subject is only half-formed and very insufficiently insisted upon.

We are all too familiarly aware how a cold runs through a family, and it must be the experience of all practitioners how catarrhal inflammations of the mucous membrane break out at varying seasons of the year, with epidemic severity. The sequelæ of so-called simple colds are in all conscience severe enough, if we accept the *ipse dixit* of the public and the general voice of the profession on the point. It therefore seems a cruel thing that we should not warn our patients and the public against the infectiousness of most, if not of all, colds, and particularly during the catarrhal stage. Important as may be the prevention of spitting that of disseminating colds is equally so. The person suffering from a cold who attends a public or private indoor gathering, perhaps with children and people troubled with delicate chests, throats, &c., is an immediate source of perilous infection.

At this season of the year a small, stuffy room, flaming gas-lights, a temperature of from 70° to 80° F., the practical absence of bright sunlight by our moisture-laden air, heavy curtains round the all too small windows, and the vitiated exhalations of the people present, seem almost perfect surroundings for the luxuriant cultivation and growth of anaerobic saprophytes.

Personally when called into a house and finding a patient suffering from cold I always warn the members of the household of its infectiveness and advise the avoidance as much as possible of all immediate personal contact. Kissing must be a common source of contagion, and children and babies are often martyrs to this injudicious custom. Good ventilation is essential in the room. From personal experience of the recent rational treatment of consumption by fresh air and sunlight I am led to believe that a great part of its efficacy is due to its largely preventing the risk of recurring catarrh.

The unfortunate owner of a cold before mixing with his fellows should carefully disinfect his oro-nasal passages, always remembering that whilst so possessed he continues a treacherous friend and a dangerous enemy.

I am, Sirs, yours faithfully,

R. PROSSER WHITE, M.D. Edin..

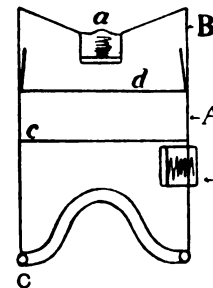

Honorary Medical Officer, Royal Infirmary, Wigan.

Oct 28th, 1901.

### A SIMPLE APPARATUS FOR ETHER NARCOSIS.

To the Editors of THE LANCET.

SIRS,—When, towards the end of last August, I was in Aix-la-Chapelle I visited a nursing-home conducted by Dr. Longard and Dr. Beaucamp, and was there shown by the former a mask for the inhalation of ether which I do not remember to have seen in this country. As this mask seems to have very definite advantages over those generally in use I venture to call the attention of those interested in such matters to the claims put forward on its behalf. It consists (see section) of a metal

mantle (A) which is closed on the one side by a funnel-shaped lid (B) and finished on the other by an indiarubber cushion (C) which forms the face-piece. In the deepest part of the lid are a few holes which are closed from within by a spiral spring valve (a), so that air finds ingress but no egress. This is the inspiration valve. The expiration valve (b) is near the face-piece. Between the valves are two horizontal fine wire sieves (c and d). The upper one is removeable, and between the two some gauze is laid. With the patient in the usual position some ether is poured on to the lid. As the patient inhales the valve opens and the fluid runs down and falls on the metal sieve (d) and thence on to the gauze. From there it passes on to the lower sieve, wetting the wires and filling up the meshes. When inhalation takes place what reaches the lungs is not pure ether, but ether which by means of the sieve arrangements has been finely mixed with atmospheric air.

The first masks which were made were found to have the disadvantage of generating ice when the atmosphere contained much moisture. This has now been remedied by the introduction of a ring-shaped thermophore which exactly fits the lid. Before the inhaler is used this thermophore is detached, heated in hot water for a few minutes, and replaced. Its presence is found to obviate the difficulties which formerly arose from the formation of a freezing mixture.

The experience of three years' constant use of this inhaler on every kind of patient may be summed up as follows: 1. Women and young men become completely unconscious in from two to three minutes, sometimes less. In older men six minutes may be necessary, but there is never any stage of excitement even in inebriates. 2. No preliminary administration either of gas or chloroform is necessary, a matter of very considerable importance to the administrator. 3. The amount of ether required for the production of complete anaesthesia is very small. For children from five to 10 cubic centimetres suffice; women require from 15 to 25 cubic centimetres, while for men, especially inebriates, from 30 to 50 cubic centimetres may be necessary. This is an appreciable saving, being about a third of what is used in the ordinary forms of ether inhalation. Lastly, the mask is exceedingly portable and does not easily get out of order. I do not know whether any of our instrument makers keep this mask, but an inquiry addressed to Dr. Longard at Aachen, Rhenish Prussia, would meet with a prompt reply. The price, I understand, is about 30s.

I am, Sirs, yours faithfully,

York-street, W., Oct. 21st, 1901.

LEONARD WILLIAMS.

### SCHOOL PUNISHMENTS.

To the Editors of THE LANCET.

SIRS,—Your interesting leading article on "School Punishments" in THE LANCET of Oct. 26th, p. 1131, opens up a subject of great importance to medical men in general and to

medical officers of schools in particular. The discreditable incident narrated therein should make every medical officer carefully inquire into the punishments inflicted in the school to which he is attached. In a properly organised school the system of punishments has been carefully thought out and the punishments graduated according to the gravity of the offence. Indiscriminate methods, such as boxing the ears, shaking by the shoulders, use of ruler, should be abolished. Your article does not mention the most valuable method of inflicting disciplinary punishment—namely, penal drill. This is performed under the supervision of the drill sergeant who sees that it is well and smartly taken. The advantages of this method are that it involves physical exertion and can be performed in the open air.

All disciplinary punishments of an ordinary class have to be entered in a public book, cause shown, and signature of the master inflicting the punishment inserted. In all cases penal marks are given which rank against the grant of extra half-holidays to the school and count against the individual in his petition for any privilege and appear in his terminal reports. Caning on the hands is prohibited and indeed should be made illegal. Caning elsewhere with a light cane only is permissible. It should be inflicted for a sufficient moral reason and not as a penalty for inferior work. The punishment is inflicted under the general authority of the headmasters by the masters and, in certain cases, school prefects. Right of appeal to the headmaster, if desired, is granted. Birching is reserved for punishment where some idea of special disgrace is to be attended. Written punishment is set for deficiency of work and consists of definite set work, not "lines." All such is entered on public sheets. All written punishments have to pass inspection by the headmaster or his delegate and bear stamp as passed for decent writing and general neatness before being negotiable with the undermasters. Returned lessons must be learnt by heart. Written punishments are done in extra-school at fixed times. All written punishment is done on special paper of conspicuous pattern. The paper may not be brought into preparation or class.

By the above methods punishment is rendered effective and consequently much lessened in amount. By inter-connexion between work and conduct-marks, which would take too long to state, but is simple and comprehensive in working, the control of discipline is greatly facilitated.

I am, Sirs, yours faithfully,

EDWIN J. TOYE, M.D. Lond., F.R.C.S. Eng. &c.,

Medical Officer of the United Services College,  
Westward Ho, Oct. 28th, 1901. Westward Ho.

## A QUESTION OF SPELLING.

*To the Editors of THE LANCET.*

SIRS,—The consistent endeavour of THE LANCET to maintain correctness in the use of English is well known, at least to those who have contributed to its pages. I was therefore not surprised to find in my lecture published in THE LANCET of Nov. 2nd, p. 1173, that the adjective which I had written "faradic" was changed by the printer to "faradaic." I do not object. I was formerly accustomed to write the word in the latter way, which seemed more in harmony with its derivation from the name Faraday and with "Voltaic"; but a reviewer took me to task for doing so, on the ground of pedantry. Such a charge is indifferent to me, but I thought it well to ask Professor Skeat's opinion on the form. His answer is of sufficient interest to be quoted entire:—"Analogy with 'Voltaic' requires the form 'Faradayic.' The names were Volta and Faraday. I can well understand that 'Faradaic' is more convenient than 'Faradayic,' but it cannot be said to be 'correct,' as his name was not Farada. In the same way Faradic is still worse, as his name was not Farad. But language does not go by what is etymologically 'correct.' Only that is really correct or right which common consent accepts and declares to be the standard. Your question cannot be decided till one or other of the forms prevails over and kills off the other. I should think it very probable that 'Faradic' will ultimately win simply because it is the shortest. Though it cannot be contended that it is 'correct,' it can be strongly urged that it is convenient, especially when you come to 'Faradisation.' 'Faradayisation' seems too much."

Professor Skeat's remarks bring out the fact that what I said in the lecture on the vitality of words is true also of spelling. Besides "faradisation" we have "faradism."

Both "faradisation" and "faradism" are certain to disappear before the more convenient forms without the "a." Hence I felt that the analogy would assuredly determine in the long run the use of "faradic" and not "faradaic," and therefore I have since employed the former. If we can discern forms which must survive in the struggle for existence we may be saved useless effort.

In connexion with the subject of spelling it is worth while to consider whether it is desirable to attempt to preserve the "w" in "whooping-cough," which dates only from about 1500. But if the "w" continues in use in the common word "whoop" the effort may fail, since the word is in such common use.—I am, Sirs, yours faithfully,

Nov. 2nd, 1901.

W. R. GOWERS.

\* \* We are grateful to Sir William Gowers for recognising our endeavour to maintain correctness in the use of English. We admit the force of Professor Skeat's remarks and have no objection to substitute "faradic" for "faradaic," but we shall continue to refuse to sanction the use in our columns of such barbarous impossibilities as, e.g., "try and" for "try to." Unfortunately they are becoming quite common even in literary quarters where we should not expect to see them.—ED. L.

## CHRISTMAS HAMPERS FOR CRIPPLED CHILDREN.

*To the Editors of THE LANCET.*

SIRS,—May I once more ask the courtesy of your columns to bring before your notice the annual entertainment, &c., to poor children in the Guildhall of the City of London, and the distribution of Christmas hampers to 4000 or 5000 little cripples. It is my privilege to have received from His Majesty the King a subscription with an accompanying letter from the Keeper of the Privy Purse, in which Sir Dighton Probyn says:—

I have the pleasure to inform you that His Majesty will be very happy to continue his support to the Christmas and New Year's entertainment which you so kindly organise every year for the benefit of the ragged-school children of London.

It is, therefore, with confidence that I again appeal to you to assist me in raising the necessary funds. The balance-sheet, signed by Mr. W. H. Pannell, C.C., chartered accountant, honorary auditor, shows that last year £1434 1s. 6d. was collected, but year by year the number of crippled children registered increases, the difficulty of selecting the recipients for the hamper becomes greater, whilst the prolongation of the war makes my task still harder. I am making a special effort to mark the advent of the coronation year by extending the hamper distribution, and to that end would gratefully receive for the Children's Fund donations large or small, to be addressed to me as heretofore at 69, Ludgate-hill, London, E.C.

I am, Sirs, yours faithfully,

W. P. TRELOAR,  
Alderman.

Ludgate-hill, E.C., Oct. 31st, 1901.

## THE HOME OFFICE ARBITRATION ON LEAD-POISONING.

*To the Editors of THE LANCET.*

SIRS.—I notice in THE LANCET of Oct. 26th a letter signed "A. Shadwell, M.D.," in which the writer says that "you are under some misapprehension" when you "speak of the manufacturers and workpeople as 'one side' and 'the other side' and imply that the Home Office is arbitrating between them, like the Board of Trade in industrial disputes," and he says that "the case is entirely different." May I ask where the difference lies? It is very evident to me that the writer has been misled by someone; the organised workers who have Lord James's permission to appear at the arbitration are certainly not on the side of the manufacturers in any sense. In eight or nine of the rules proposed we believe that they require strengthening; while Rule 6, which I believe was inserted at the request of employers, we feel we must object to so long as the Workmen's Compensation Act is not amended so as to include all cases of lead-poisoning. In reference to Rule 2, which is bound to provide a great deal of argument for and against on the part of the experts, our interests will be watched by counsel and we hope that some-

thing will be done to protect the health and lives of the lead-workers without in any way injuring the trade of the district. Dr. Shadwell would have been somewhere near the mark if he had said that the Home Office was between the two of us, the manufacturers saying that the proposed new rules are too stringent, while we (the workpeople) say that many of the rules are not stringent enough. Perhaps the best way of putting the case is to describe it as a three-cornered contest, in many portions of which the views of the operatives are directly antagonistic to the amendments of manufacturers.

I am, Sirs, yours very sincerely,  
N. PARKES,  
General Secretary, Printers' and Transferrers' Trade  
Protection Society.

Burslem, Staffs, Oct. 29th, 1901.

## EFFICIENT REVACCINATION.

To the Editors of THE LANCET.

SIRS,—Nothing will do so much harm to the credit of vaccination as the employment of inert or very feeble lymph. Complaints as to the quality of the lymph which ordinary practitioners are now able to get are very general, and it is not easy to see why the organisation of the Government supply of vaccine lymph should not be enlarged so to meet the demands of all practitioners, but till this is done other methods of improving the supply of trustworthy lymph may be considered. I venture to suggest two such methods. 1. The British Medical Association might employ inspectors of the commercial vaccine lymph manufactories. These inspectors should, of course, be familiar with the best methods employed in the Government laboratories here and in Germany and they should pay frequent and surprise visits to the manufactories and report at short intervals in the medical papers for the guidance of practitioners in need of lymph, grading the manufactories according to the excellence of the methods employed. 2. Reports as to the actual value of the various commercial lymphs as tested by experience might be published once a month in the medical papers, the name of the firm that supplied the lymph being given with each report. If a large number of general practitioners would take the trouble to send to THE LANCET and to the *British Medical Journal* month by month a record of all their vaccinations and revaccinations, mentioning for each case the source of the lymph used and the number of vesicles produced, the inducement to sell only active lymph would be materially increased. If Germany can efficiently revaccinate a population of 55,000,000 it ought not to be impossible to produce in England enough active lymph for our much smaller numbers.

I am, Sirs, yours faithfully,  
E. GARRETT ANDERSON.

Upper Berkeley street, W., Nov. 2nd, 1901.

## GUY'S WILL.

To the Editors of THE LANCET.

SIRS,—Reference to a copy of the first edition (1725) of Guy's will in my possession shows that the statement in the extract from the "Dictionary of National Biography" which appears in THE LANCET of Nov. 2nd, p. 1208, is slightly inaccurate; the four, six, or eight persons to be apprenticed or nursed ("or such like charitable deed") were "of the family of the Voughtons or Woods or proceeding therefrom." "Two or more such poor persons of the family of the Guys or proceeding therefrom" were to be similarly benefited. The Voughtons were Guy's cousins. The relationship to the testator of the Guys benefited under the will is not stated, but they received a smaller legacy than many of the other beneficiaries—viz., "Five Hundred Pounds a-piece." They were "Margaret Guy and Samuel Guy, the children of Samuel Guy, late of Egham in the county of Surrey."

My copy of the will contains a number of interesting manuscript notes, amongst them a statement that notices of Mr. Guy are to be found in "British Chronologist" (1789) under the year 1724, vol. ii., p. 94, and in Hughson's "London," vol. i., pp. 118, 119, and vol. iv., pp. 461, 462; also an alphabetical list in manuscript, dated Feb. 17th, 1744-5, of the "First and Present Presidents and Governors of Guy's Hospital." A marginal note, which bears evidence of having been written by a former owner of the book in 1835, states that the will is "now in prerog. office." I suppose this means the office of the Prerogative Court of

Canterbury. Is the original will now at Somerset House, or where? I am, Sirs, yours faithfully,

HERBERT R. SPENCER, M.D. Lond.

Harley-street, W., Nov. 2nd.

## RE SPASTIC PARAPLEGIA AND RETINITIS PIGMENTOSA: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—With reference to the account of the proceedings of the Society for the Study of Disease in Children in THE LANCET of Nov. 2nd, p. 1200, the report of my remarks is misleading and may give rise to confusion. De Amicis (of Naples),<sup>1</sup> in a paper on the Relationship of Spastic Paraplegia (Little's disease) with Syphilis, gives the details of a case of spastic paraplegia in a boy, aged three years, whose father and mother had undoubtedly suffered from syphilis. I did not say that in de Amicis's case there was retinitis pigmentosa. I referred to it as in favour of the syphilitic origin of the case of spastic paraplegia with retinitis pigmentosa shown for Dr. Garrod, in which the eye condition was considered to be suggestive of syphilis.

I am, Sirs, yours faithfully,  
GEORGE PERNET.

Upper Gloucester-place, N.W., Nov. 2nd, 1901.

## ACUTE DILATATION OF THE STOMACH.

To the Editors of THE LANCET.

SIRS,—The letter of Dr. William Ewart in THE LANCET of Nov. 2nd, p. 1228, upon acute dilatation of the stomach has suggested another reference to the cases mentioned by me. It was not until I had left the post-mortem room, after examination of the more recent case, that I remembered having read of the theory that obstruction of the duodenum may be occasioned by pressure from the superior mesenteric artery, and the possibility of such a cause for the dilatation was, unfortunately, not definitely excluded. The duodenum was, however, less distended in the third part than in the first and second portions, and the jejunum, although not abnormally distended, was certainly not collapsed. In the other case mentioned in my letter it was also the first part of the duodenum which was most markedly distended.

The theory to which Dr. Ewart has drawn attention is interesting, but it is difficult to believe that so simple a form of obstruction can lead to a distension of the stomach which may bring the greater curvature as low as the pubes. Theories which attribute morbid conditions of the digestive tract to the influence of the nervous system are perhaps vague, but it is not easy to account for some of these conditions unless one believes that the nervous system has played some part in the causation. For example, I have seen in two instances extensive hæmorrhage into the coats of the small and large intestine extending without a break from the junction of the duodenum and the jejunum to the hepatic flexure of the colon. The fact that the transverse colon was unaffected showed that the whole of the area of the distribution of the superior mesenteric artery had not been involved in the hæmorrhage, and careful examination of the superior mesenteric artery and vein, together with their branches, revealed no trace of either embolus or thrombosis. The precisely similar distribution of the hæmorrhage in these two cases—a distribution which did not closely follow the area of supply of a blood-vessel—suggested that the nervous system had played some part in the causation of the bleeding. It also suggested that the jejunum and ileum possess an innervation which is presided over by centres which govern also the innervation of the cæcum and ascending colon. If this be true then the stomach and duodenum may also possess an innervation common to both, disturbance of which, while not primarily responsible for some morbid condition of these viscera, may occasionally determine its nature. In the two cases of acute dilatation of the stomach and duodenum mentioned by me the primary cause of the dilatation appears to have been the septicæmia which was present.

I am, Sirs, yours faithfully,  
Clifton, Bristol, Nov. 2nd, 1901. THEODORE FISHER.

## THE MENTAL FUNCTIONS OF THE BRAIN.

To the Editors of THE LANCET.

SIRS,—I have to thank you for the review of my book on "The Mental Functions of the Brain," which appeared in THE LANCET of Oct. 19th, p. 1051. If, as your reviewer says: "The work is a pretentious one and its claims are of an exceptional character," it seems to me a pity that he should have ignored one-third of it, containing some important statements, which—if they are not true—require immediate contradiction. It is stated in the book:

1. That there is not one man of scientific repute who has written anything which would indicate that he has examined Gall's chief work on the Anatomy and Physiology of the Nervous System. 2. That Gall's discoveries, anatomical and physiological, particularly the former, were ignored even by his most scientific followers, so that the world is ignorant of them. 3. That any one of the numerous anatomical discoveries, presented for the first time in this book, should have sufficed to bring Gall fame, but that there is not one text-book in the United Kingdom dealing with the anatomy of the brain which even mentions his name. 4. That his localisation theory has been misrepresented throughout the past century and most actively by those who found the principles of his doctrine useful but wished to hide the fact to escape the popular bias against phrenology. 5. That as a consequence of this foolish opposition for a whole century we still disagree even as regards such a fundamental localisation as that of the *intellect*. One school considers the frontal lobes to be the seat of the higher intellectual operations, another the occipital lobe, Rüdinger the upper part of the parietal lobe, Professor Cunningham<sup>1</sup> the lower part of the parietal lobe. Whereas Gall has collected for many of his investigations clinical, pathological, and experimental evidence, some of the recent observers advocate the method of looking for "protuberances." 6. There are many other important statements in the book. To give one more example, Gall has described the first genuine case of "aphasia" (see p. 230), yet we still give Broca the chief credit, and those who acknowledge Gall often speak of his discovery as a "mere happy guess."

By ignoring this part of the book your reviewer makes it appear as if I were reviving the phrenology of the self-styled "professor," and thus, unintentionally, excites the prejudices of the readers of his review against the book.

Now as to the "*several*" post-mortem records which I am supposed to quote in support of the theory that the lesion in irascible insanity and violent mania is to be found in the temporal lobe. My "*several*" records number 350, the majority of them being injuries to the temporal area, localised tumours, and circumscribed inflammatory disorder. The minority are cases in which a lesion took place in some adjoining part, but involved the temporal lobe by extension. Your reviewer selected one of the latter cases as a "typical instance of my method of stating facts and deducing conclusions." Unfortunately this is one of the three cases (out of 800) which got into the book by some error and was marked by me for "revision" or "omission" for the second edition. I acknowledge my responsibility, but to describe this case as typical of the 350 quoted in favour of the localisation of irascible insanity is clearly a misrepresentation. I have had to quote my cases as I found them in the clinical records, foreign cases having been translated and the British cases left unaltered except for the condensation where necessary, so that in most cases the authors themselves are responsible for their records.

However opinions may vary as to the value of the deductions at which I have arrived your reviewer is the first not to acknowledge the vast amount of material which I have collected in this book for the benefit of future investigators; and considering the absence of positive knowledge as regards the mental functions of the cortex, the growth of the brain, the significance of its size and weight, investigators can little afford to sneer at an honest attempt at an elucidation of these problems, such as I have made.

I am, Sirs, yours faithfully,

London, Oct. 21st, 1901. BERNARD HOLLANDER, M.D.

<sup>1</sup> See Presidential Address, British Association (Anthropological Section), Glasgow, September, 1901.

## THE ETHICS OF THE PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—Owing to the complaints one hears upon all sides as to the elastic manner in which some of the public vaccinators are interpreting the duties of their office I have ventured to submit to you a series of questions which are not without interest to general practitioners at the present time.

1. Should a public vaccinator who is appointed to a definite district vaccinate anyone who comes to his house, irrespective of where they reside, or should he find out their address and refer them to the public vaccinator of that district?

2. Can a public vaccinator charge the authorities for work done by his qualified assistants to whom he pays a salary of three or four guineas a week?

3. Should a public vaccinator interview the principals of large firms where he knows there is a regular medical attendant and induce them to allow him to vaccinate their employés under the plea of gratuitous operation?

4. In the event of his vaccinating a large staff should he ascertain whether any of the members who live at home would prefer to be vaccinated by their own private medical attendants?

5. If when making a house-to-house inspection a public vaccinator finds that certain of the inmates intend to be vaccinated by their own medical men, is he justified in persuading them to be operated upon by himself on the grounds that he will do so free of charge?

6. Is it a professional act for a public vaccinator to attract children by means of chocolates, apples, &c.?

Will you kindly publish the fees which are now being paid per head to public vaccinators in the different districts of the county of London. The medical profession will have to pay their share of the vaccination rate, and this in some cases will mean paying for the vaccination of our own patients.

I am, Sirs, yours faithfully,

Nov. 4th, 1901.

GENERAL PRACTITIONER.

## A SANITARY OUTRAGE.

To the Editors of THE LANCET.

SIRS,—Will it be believed that the Westminster City Council erected two stands for themselves and their friends in the Green Park opposite Devonshire House over the two public urinals which exist at that spot, necessitating the closing of these necessary conveniences for the whole of Friday and Saturday last? Their friends doubtless appreciated the invitation to lodge in the W.C. district and, I hope, enjoyed their visit, but I should like to know whether the Westminster Council had the right to interfere with the comfort of thousands who were thus forced to relieve the wants of nature in the neighbouring park.

I am, Sirs, yours faithfully,

Nov. 4th, 1901.

AN OLD PRIVY COUNCILLOR.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague Epidemic.—Plague Administration in Bombay City.—The Famine and the Rains.—Deaths from Wild Animals.—The Victoria Scholarship Fund for Training Native Midwives.—Cocaine-eating in Bengal.*

THE mortality from plague throughout India is still increasing. The outbreaks in the Belgaum and Dharwar districts of the Bombay Presidency have further developed and account for the greater number of deaths. The disease, moreover, is spreading in the Punjab and at Poona. For the latter health camps have again been opened. Since the recrudescence which commenced in August 112 cases have been reported. In the Punjab the cases have increased during the past week from 181 to 301, and 15 deaths are reported from the province of Jammu. In Bombay city the deaths from plague are somewhat fewer, and in Calcutta the number fluctuates week by week between 12 and 20.

A great change is in course of operation in the plague administration of Bombay city. The Commissioner still remains the head of the department, but immediate

orders will now issue from the health officer. The same policy will be pursued, but it is hoped that plague will be treated under the Municipal Act as an ordinary epidemic disease and as such will be properly dealt with by the Health Department to the exclusion of any outside interference. This is as it should have been treated from the very first. The same arrangement would be equally applicable to Calcutta. In Bombay an army officer has hitherto controlled operations. Now that all heroic measures have been suspended a separate organisation for plague is not wanted. There will also be a considerable saving in expense—a matter of no small importance for other places as well as for Bombay.

It is hardly realised at home that the famine still continues and that there are about 300,000 people receiving relief. The past season has not been everywhere favourable. Baluchistan has had only a tenth of its normal rainfall, Gujarat only one-third, Central India and Rajputana about a half, while parts of the Deccan are 20 per cent. behind.

The mortality from wild animals in India is another matter not fully recognised. Last year it was very large. Snake-bites are reported as having caused 22,393 deaths and bites of leopards and jackals 980 deaths. Tigers killed 943 people, elephants 36, bears 97, and wolves 424. Parts of Bengal suffer most from tigers, one man-eating tiger having caused 47 deaths. In addition to human beings there were no less than 81,890 head of cattle killed. It is satisfactory to learn that 17,250 wild animals were destroyed besides 88,232 snakes.

The Victoria Scholarship Fund for training native midwives in India continues to receive widespread support and up to the present time over five lakhs of rupees have been subscribed. Judging from the death lists issued in some of the cities the total mortality of women in childbed must be enormous, and it is probably as great, if not greater, in the rural districts. Crass ignorance and filthy habits seem to be the causes of this high mortality.

The habit of cocaine-eating seems to have spread extensively among the natives of Bengal. The ordinary *pan*-sellers are the chief distributors. It is sold in small paper packets containing either half a grain or one grain which are obtained for half or one anna respectively. It is impossible to say how much is consumed by any one individual, but several grains a day have been confessed to. The sense of feeling well is followed by depression, but the habit appears to be peculiarly seductive, and once commenced is with the greatest difficulty abandoned. A blackening of the teeth is said to be caused by cocaine-eating and the blackening is thought to be characteristic. It is said to be most marked in the lower teeth and on the inner or posterior surface, and to be quite different from dirt or the staining of tobacco. The general symptoms are those of cachexia with a sallow look, sunken eyes, and emaciation.

Oct. 19th.

## THE LEGAL STATUS OF MIDWIVES.

(FROM A LEGAL CORRESPONDENT.)

[OUR readers have had so many occasions of hearing our views on the midwives question that they will know how far we can go with the opinions expressed in the following article. But it is well that they should read the public view of the question temperately and logically expressed.]

Judging from the correspondence in the medical press and the addresses of some of the candidates for election as Direct Representatives on the General Medical Council much misconception prevails amongst medical practitioners as to the existing legal status of midwives. Mr. George Brown, for instance, who is seeking re-election to the Council, having taken full credit in his address for his opposition to the Midwives Bill of last session, proceeds thus: "Much will depend upon the votes recorded in this election, and you may rely upon me that my opposition to legalising midwives as independent practitioners will be as keen as ever, and I should like both midwives and all unqualified practitioners made legally responsible for any damage they may cause to mother or child or any other person." Mr. Brown's colleague, Mr. George Jackson, having referred in his address to the action he took at the last election to the Council, goes on to say: "I am

now as then opposed to the registration of midwives, the creation of an inferior order of practitioners." These two candidates for the honour of directly representing their profession on the General Medical Council have apparently yet to learn that midwives are fully "legalised as independent practitioners," that "both midwives and all unqualified practitioners" are "legally responsible for any damage they may cause to mother or child or any other person," and that this particular "creation of an inferior order of practitioners" was accomplished several centuries ago. When the order of midwives was created it would be as difficult as useless to discover, but we do know that here in England some four centuries ago the bishops, who were then the licensing authorities for physicians and surgeons, licensed midwives also. They continued to license surgeons and midwives down to the middle of the eighteenth century. The College of Physicians of London about that time took over from the bishops the charge of examining and admitting midwives to practise, a charge which they renounced some 80 years ago. Since that time any person who chooses may undertake the important duties of midwife. No test of competency for the office is imposed by any responsible authority and so the public are left to such protection as the common law affords against the *malpraxis* of uninstructed practitioners.

By the common law of England a person is entitled to practise in any profession or business which he thinks fit to adopt, but he practises at his peril—that is to say, if he is grossly ignorant of the profession or business of which he holds himself out to be a master he is liable to be punished by fine or imprisonment as guilty of a misdemeanour, whilst the injury suffered by any person from such ignorant practice is a private wrong for which damages are recoverable. In the case of one undertaking the office of a midwife, as in that of a registered medical practitioner, the law implies not that she will bring her patient safely through the perils of childbirth, but that she will use reasonable professional skill and due diligence to that end (*Lanphier v. Phippos*, 8 C. & P. 475). When, however, the practice of a profession is of such a nature that the incompetency of the practitioner is always attended with dangerous consequences and not infrequently with irremediable or even fatal consequences the common law protection is plainly inadequate. Hence the necessity of prescribing by statute the qualifications of those who enter such profession. This has been done in the case of the medical profession by the Medical Acts of 1858 and 1886; and chemists and druggists have been brought under similar statutory control. That midwives have not yet been brought under any statutory control, notwithstanding the dangerous nature of their duties, is, I consider, a serious defect in medical organisation. The Medical Act of 1886 which made it obligatory on all candidates for medical registration that they should pass a qualifying examination in midwifery of such a standard of proficiency as to guarantee the possession of such knowledge and skill as is requisite for efficient practice made no provision for regulating the business of midwives and bringing it under the supervision of the General Medical Council or some other body created *ad hoc*. This omission remains to be repaired. Although at the bottom of the medical hierarchy the midwife cannot be ignored. Unlike the unregistered medical practitioner she can recover reasonable remuneration for her services in a court of law. Such services have been held in a recent case to be "medical or surgical assistance" within the meaning of that phrase in the Medical Relief Disqualification Removal Act, 1885 (48 & 49 Vict., c. 46), (*Honeybone v. Hambridge*, 18 Q.B.D. 418).

It must be confessed that little progress has been made in recent years towards the settlement of the midwives question. The want of an examining and licensing authority for midwives has been long felt by a section at least of the medical profession. In a learned treatise on medical jurisprudence published in 1823, the joint work of an eminent Fellow of the College of Physicians and of a distinguished member of the bar,<sup>1</sup> there is this footnote to the case of *Dr. Letch v. College of Physicians*: "It is said that the College [of Physicians] have determined not to interfere for the future with the licensing of midwives; the policy of this resolution is very questionable, for the examination and licensing of persons in all branches of medicine is a public duty imposed upon them which they are not at liberty to abandon or execute at their pleasure. It may be urged that

<sup>1</sup> By J. A. Paris, M.D., F.R.S., F.L.S., F.R.C.P., and J. S. M. Fonblanque, Barrister-at-law.

this branch is rather surgery than physic, but as the College have once assumed the jurisdiction it is doubtful whether they ought to relinquish it. The surgeons might also disavow their obstetric brethren and then the matter must revert as of old to the bishops who cannot be supposed to be the most competent judges of the necessary qualifications." Recurring to the subject under the head of "Midwifery" the learned authors observe: "We have before noticed that there is some probability that both the College of Physicians and the College of Surgeons will decline all future interference with this branch. If so it will be necessary that some new authority should be instituted for the purpose of examining and licensing candidates for practice; the duty to be performed is by far too dangerous and delicate to be left in the hands of any who would assume it, yet such is at present the case, and not without fatal examples of the errors and imperfections of our lego-medical system." Referring to the voluntary organisations of their day for the training of midwives, they add: "We do not, of course, include in this censure the private institutions for the instruction of midwives in which the want of a public provision is endeavoured to be compensated; but the operation of such societies must be of necessity very limited and utterly inadequate not only to the demands of the empire, but to the magnitude of the metropolis."

This might very well be written to-day, so little has it lost in force by the efflux of time. The licensing of midwives is still the *quæstio vexata* it was when these learned authors wrote. There is no justification for it remaining so. The General Medical Council has been created since then and might well have its jurisdiction extended so as to include the supervision of midwives. There is no insuperable difficulty in framing such a definition of a midwife's office as will exclude the possibility of her infringing on the sphere of the medical practitioner. An ignorant untrained midwife is far more likely to embark on rash and reckless treatment of her patient than one who knows from the training which she has received when the case has passed the limit of her skill and should be attended by a medical practitioner.

## SANITATION AT EDINBURGH.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 1160.)

WHILE the corporation have displayed so much public spirit and enterprise in creating what may be described as a palatial fever or isolation hospital, private charity and enterprise have conferred on Edinburgh the honour of being the first town in Scotland which has attempted to establish a sanatorium for the outdoor treatment of pulmonary tuberculosis. The Victoria Hospital for the Treatment of Consumption was opened on March 31st, 1900. In Scotland some 7000 deaths are annually attributed to this disease and it is reckoned that the mortality from this cause is equal to about 500 deaths annually among the inhabitants of Edinburgh. To ascertain the number of persons actually suffering from this disease these figures may be multiplied by 10. In his last annual report the medical officer of health, Sir Henry Littlejohn, states that phthisis caused 548 deaths in 1900 in Edinburgh, and there were 270 deaths from other forms of tuberculosis. In dealing with this scourge Sir Henry Littlejohn follows the lead of the continental sanitary reformers and insists that the authorities should exercise all their influence to prevent expectoration in the streets and on public conveyances. He also points out that as the system of flats prevails in Edinburgh the common staircase is a source of danger. This remark, it seems to me, applies more to the better-class houses than to the new or model artisans' dwellings. In the latter the staircases are generally exposed to the open air and are not protected by windows. In some high-class houses let out in flats I have found the staircase very dark and the windows generally closed. Such staircases should, therefore, be kept scrupulously clean so that the dust from them should not be conveyed into the apartments. The staff of sanitary inspectors have received instructions in regard to this matter, but it does not seem as if anything effective has been accomplished. To expectorate in a dark, badly ventilated, and not very clean staircase may amount to laying on phthisis just as

water or gas is laid on to a house. The Edinburgh Health Committee have issued upwards of 30,000 cards warning the inhabitants of the danger and indicating a few simple precautions. The railway companies have also been approached and the municipal tramways servants have instructions to prevent spitting on the floor of these vehicles.

As with the isolation of infectious fever cases, so also in the treatment of phthisis, a double advantage is secured. Not only does the patient benefit by a better chance of recovery, but there is less danger of his spreading his complaint to others. The system of house accommodation in Edinburgh, together with the climate, afford but small prospect of recovery. According to Sir Henry Littlejohn the principal hope rests in the early recognition of the disease and immediate departure for foreign countries and for high, bracing plateaux. But this is only possible with the wealthy. Sir Henry Littlejohn, however, raises the question as to whether the town council would be prepared to incur the expense of sending abroad experimentally some hundred or more carefully selected patients from among the poor, but he thinks that our colonies might object to receive these damaged lives. For my part, I would suggest that it is not absolutely necessary to go to the colonies. In Switzerland and on the Riviera there are many places which depend for their very existence on the presence of a large number of phthisical patients. There is no reason why these countries should object to hospitals established by foreigners with foreign money any more than they do to their own similar institutions. Such action should not be opposed, for it would be an excellent advertisement for the whole neighbourhood. The principal difficulty is a question of finance, and this would be met if the number of definite cures obtained was such as to constitute a considerable relief to the rates and to the charities of the town or district that ventured upon so bold an enterprise.

Sir Henry Littlejohn also raises his voice on behalf of the respectable citizen who has earned his living and has paid his taxes regularly, but who, having contracted phthisis, is dismissed by his employer. Should such a man be ultimately driven to the workhouse or should the town council provide some resting place "where, though the case is hopeless, every effort would be made by medical skill and comfort to afford ease of mind and body, while the family, relieved from the cares of nursing and the expense of maintenance of an exacting invalid, would be able to make fresh arrangements for keeping the household together and fighting the battle of life." Putting the claims of humanity aside and considering this proposal from the mere utilitarian point of view, the carrying out of some such suggestion might, in the long run, prove the cheapest. It might prevent whole families from sinking into the pauper ranks and would lessen the risk of spreading the disease by doing away with a centre of contagion. Sir Henry Littlejohn has also come to the conclusion that compulsory notification of consumption should be enforced. He claims that Edinburgh was first among the large towns to promote, in 1879, a private Bill for the compulsory notification of infectious diseases. This spirited action so helped to spread education on the subject that, in 1889, the Government was able to pass a similar Act applying the principle of notification to the whole country; and now it is urged that Edinburgh should again take the lead by having this principle extended to cases of pulmonary consumption.

Apart from such endeavours to prevent the spread of phthisis, Edinburgh, as already mentioned, has taken the lead, so far as Scotland is concerned, in applying the most recent methods to effect the cure of phthisis. The promoters and patrons of the Victoria Hospital for the Treatment of Consumption in their last annual report maintain that thousands of persons unnecessarily lose their lives and slowly sink into a state of physical and financial bankruptcy because there are not any means available by which they can obtain proper treatment. This is the more deplorable as the record of sanatoriums in all parts of the world show that cures can be effected by the open-air system of treatment. Even now it is only on a very small scale that Edinburgh has found the means of practically demonstrating what can be done. Though the first hospital in Scotland for the outdoor treatment of phthisis claims that it is not a local but a national institution, it only possesses 23 beds. Already for one patient admitted there are at least 10 applicants. Fortunately the grounds secured are sufficiently spacious for other buildings to be erected. A beautiful park which slopes towards the south has been obtained and the residence has

been converted into a hospital. Already and during the first three months an annex has been built and furnished, holding eight patients, for the small cost of £800. Every £1000 obtained will provide accommodation for from eight to 10 more patients. So great was the demand that a system of visiting patients had to be organised. The latter do not sleep at the hospital, but they remain there all the day, profit by the treatment, and enjoy the hospitality of the institution. Of course this is not so satisfactory, for the *régime* cannot be properly carried out at night by the patients in their own homes.

From March, 1900, to March, 1901, there were 115 indoor patients. With but few exceptions all those who resided in the hospital progressed satisfactorily and "a considerable proportion have, on discharge, been able to resume regular work." These latter are not lost sight of but are encouraged to report themselves from time to time. The outdoor patients are given printed instructions concerning the treatment and prevention of the disease and thus useful educational work has been done. The bedridden patients are visited in their own homes by the outdoor medical officer and he always makes a point of instructing the friends and relatives how to limit the spread of the disease. Then there is a Samaritan Committee giving financial help where there is need.

When I visited this hospital it was the morning following a boisterous night. In one of the rooms I found a large pool of water on the floor. This was caused by the rain which had been blown in through the window left wide open in spite of the patients who had slept in the room. Now the patients were all out in the gardens sitting over the wet grass and wherever they could catch the fleeting sunbeams. Several of them had bared their chests to the sun and the skin was brown through constant exposure. Some of the patients had slept out all night in wooden structures shaped like Dutch ovens. These can be moved so that their backs are against the wind and thus the rain does not fall on the beds, which on the front side are in no wise sheltered. Dr. R. W. Philip, physician to the hospital, showed me a number of charts which set forth the wonderful and rapid reduction of temperature which follows on the outdoor treatment. Within two or three weeks the night sweating also, and almost invariably, disappears and this without the use of any drugs. The loathing for food is replaced by a greedy appetite. The weight of the patient increases, his colour improves, and cough and expectoration become less and less frequent. Dr. Philip further states that there is no limit to the application of the method "provided there is a wise discrimination in respect to details." The results vary in degree; improvement is the rule but a permanent cure can only be expected in cases of pulmonary tuberculosis which are taken in hand sufficiently early. Perhaps the most remarkable fact about this hospital is its successful establishment in such an unlikely climate as that of Edinburgh. If the outdoor treatment is feasible in such bleak and northern latitudes, how much more effective might it become in sunny latitudes where the climate would be a natural ally to the methods employed.

Apart from these specific and direct endeavours to reduce the prevalence of pulmonary tuberculosis, it is notorious that general sanitary improvements have greatly mitigated the fatal effects of this disease. Prominent among such reforms is that of the better housing of the poor. In the city of Edinburgh this question has not been neglected. £150,000 have already been spent under the Housing of the Working Classes Act. Whether this money has been wisely spent is another question. In any case some of the city fathers freely recognise that grave mistakes have been made. Certain it is that the worst portion of the sore has not been touched. It has been argued that the houses put up by the corporation were too good. Slums were demolished but the inhabitants of these slums have not been re-housed. As is usually the case a much better class of tenants came and inhabited the model dwellings erected on the sites of the ancient slums. At present it seems as if no attempt is made to deal with the residuum. The lowest class object to the corporation tenements on the ground that they are too bright, too clean, too good, and that they have not furniture decent enough to put in them. More important than these objections is the fact that they do not want to live clean, decent, orderly lives and dread the control which the municipal authorities might attempt to exercise over them. In this respect the Edinburgh Corporation have hit upon an expedient which, just because it gives excellent

results with a more respectable class of tenants, is well calculated to drive away the disreputable residuum. Instead of collecting the rents themselves or appointing a factor to do so this work has been intrusted to a philanthropic society. Ladies belonging to the Edinburgh Social Union receive a commission of 5 per cent. for collecting the rents; but they do much more than merely collect the rents. They strive to become the friends and advisers of the tenants, helping them by timely suggestions to keep their homes clean, tidy, and healthy. It has been my privilege to visit several of these municipal tenements and the order that reigned within was certainly superior to the general run of habitations frequented by the same class of tenants. But all this leads to the institution of a process of selection and thus the municipal housing scheme has resulted in help being given to decent labouring men who are honestly striving to do their best with the slender means which they possess. Of course, this in a sense is very satisfactory, but it does not meet the great sanitary problem created by the thriftless disorderly residuum whose overcrowded, dirty, unhealthy homes are a perpetual menace to the health of the community. This, the lowest, section of the population is still left to occupy the old houses which have degenerated into tenement dwellings.

In dealing with this most difficult problem the town of Edinburgh possesses special advantages. It has under local Acts unlimited borrowing powers. Strange to say the only limit imposed is in regard to electric lighting. Money for this latter purpose cannot be borrowed except with the assent of the Secretary of State for Scotland. Further, as there is no limit to the powers of assessment which the corporation possess they are able to borrow at a cheaper rate. On the other hand, the local Act enforces the repayment of moneys borrowed for housing schemes within a lapse of 30 years. The result is that these schemes cannot be made to repay the cost in so short a time and therefore a part of the expenditure has to be raised out of the rates. But as yet this has only involved the citizens of Edinburgh in an extra rate of a half-penny in the pound. The gross rental of the four schemes that are now completed is £2066. The general and working expenses, the taxation, repairs, and maintenance, are set down at £512 annually and the interest on the loan amounts to £1350 and the sinking fund to £1530. These make a total of £3392, and, deducting the income, an annual deficit of £1326 is shown, which has to be charged on the rates. No ground-rent has to be paid because the ground belongs to the old borough of Edinburgh. By this it will be seen that the community is paying to-day for the creation of a property which at the end of the 30 years will be profitable. All this, however, does not meet the most urgent need. Taking the annual report for 1899 drawn up by Mr. John Cooper, the borough engineer, it will be found that this deficiency is frankly acknowledged. He admits the improvement effected in the sanitary condition of the new houses, but he adds that "people cannot live on sanitary conditions alone, however superior." The labouring man, if in work all the year round, might earn a maximum income of 24s. a week. It would be still more than the average if his income was estimated at 20s. a week and it would not be prudent to expect more than a tenth of this, or 2s. a week, for rent. In actual practice, however, a regular payment of 2s. a week for rent cannot, Mr. Cooper says, "be considered as at all reliable." There are, he insists, many respectable families whose incomes are very precarious and fall considerably below £1 a week. The rentals of the model dwellings provided vary from £5 to £10 10s. per annum, or about from 2s. to 4s. a week. They are, therefore, better suited for the skilled artisan than for the labourer. To reduce the cost Mr. Cooper suggests that, in dealing with a slum area, the powers conferred by the Housing of the Working Classes Act are not designed to enable house factors and owners of property to allow dilapidations and insanitary conditions in the hope that the local authority will ultimately be compelled to buy up such property at from eight to 12 years' purchase for the purpose of pulling it down. Such a course would defeat the purpose of the Act. When a property is really uninhabitable the compensation paid should be based on the value of the building materials, less the cost of removal, and the site occupied. This and not more, the borough engineer insists, should be paid for such insanitary houses. Even on these conditions the land in central positions would be too expensive and the Corporation of Edinburgh are seriously considering whether they should not avail themselves of Part III. of the Housing of the Working

Classes Act to purchase unoccupied suburban areas and run cheap means of transit to these localities. There are still some 2000 acres of land within Edinburgh, exclusive of parks and gardens, which have not been built upon, and recent legislation has conferred the power to purchase outside the municipal boundaries. Thus, taking all these circumstances under consideration, it may be said that the Corporation of Edinburgh have barely passed the threshold of the great question which is perplexing the municipalities of all the great and populous centres.

In regard to other sanitary work it may be said that the registration of plumbers combined with active sanitary inspection have greatly contributed to improve the domestic drainage of private houses. The public sewers, however, are probably in need of considerable improvements. Some sewers are well graded, consist of pipes in which the sewage runs freely, and few if any deposits are made. Others, on the contrary, are stone-built, rough, and likely to retain heavy substances, though, on the whole, there are but few complaints as to bad odours. Nevertheless, it seems evident that the system of ventilation, or the traps, are not always efficient. Mr. Cooper relates that some refuse from an oil-gas manufactory found its way into the St. Cuthbert's-lane sewer and thence into the Nor' Loch outlet sewer. It came in contact with some heated liquid and a strong smell of paraffin resulted. This was not confined to the sewers and sewer ventilators, but very rapidly invaded the cellars and front areas of a great number of houses—a fact which showed that many connexions between private houses and the sewers were defective. Improvements were consequently effected here and there which might have been neglected but for the accident that rendered their necessity so evident. Considering that Edinburgh is a very old town and that the sewers have been built at different epochs, some being very ancient, there are probably many discrepancies. It would be well, therefore, if all the sewers could be examined, a complete survey of the whole system taken, and a detailed report given. Doubtless this will be done at no very distant date. Though there still remains much to engage the activities of sanitary reformers, Edinburgh has acquired a prominent place among the towns that have set a good example.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Precautions against Plague.*

ALTHOUGH no cases of plague have, so far as is known, occurred in Manchester, it is satisfactory to learn that the authorities are taking proper precautions. Dr. J. Niven has issued a circular to the medical practitioners in which he draws attention, as a matter of the gravest kind, to the great number of rats in Manchester, as in other large cities, and to the condition of the middens and ashpits. He also says that increased attention should be given to the cleansing of dirty houses and that the powers possessed by the corporation should be freely used to enforce it. As a matter of precaution plague should be added to the list of notifiable diseases, to which also in the actual presence of the disease it would be desirable to add pneumonia. Mr. C. H. Tattersall has also issued a somewhat similar circular to the medical practitioners of Salford. Dr. Pringle, medical officer of health of the port of Manchester, read a special report yesterday to the port sanitary authority in which he said that from the preventive point of view rats presented much greater difficulty than man. By the Cholera Regulations of 1897 Liverpool was bound to inspect all ships coming from foreign infected ports, to isolate any cases of plague discovered, and to disinfect the ships. Dr. E. W. Hope, medical officer of health of Liverpool, has assured Dr. Pringle that Manchester-bound ships from infected ports should receive every attention. All ships from infected ports are now to be moored at a certain distance from the dock walls and the cables are to be provided with rat-guards. He recommended fumigation with sulphur for killing the rats on board ship. In order to supervise the barges and flats he said that another inspector should be appointed, and that the length of the port (36 miles) rendered the acquisition of a steam launch almost a necessity. There is no doubt that the port authority are quite alive to the importance of preventive measures against one of the "most terrible scourges" to

which man is liable, and that Dr. Pringle's suggestions will be promptly carried out.

### *Water-Supply.*

With the long-continued deficiency of rainfall over the Longdendale gathering area the water-supply of Manchester has been gradually lessening, and yesterday there was only enough water for 20 days. The weather, of course, is uncertain, and it may change at any time, but it looks as if there would be a continuance—when outside the Manchester smoke and fog—of fine bright days and nights. Thirlmere can only give the 8,000,000 gallons daily brought by one pipe, though there is plenty and to spare in the lake, and so it seems to mock us as Tantalus was mocked.

### *Unprotected Fires.*

At an inquest held at Bury last night on the body of a child who died from burns the coroner said that the Coroners' Society had been collecting statistics which showed that "something like 75 per cent. of the burning cases in relation to children had been caused by the fire-grates being unprotected." He fancied that it would not be long before parents would be compelled to guard their fires. For the children's sake it is to be hoped that he is not too sanguine.

### *Health Teaching in Board Schools.*

On Oct. 4th a deputation from the Manchester and Salford Sanitary Association attempted to induce the Manchester School Board "to consider the advisability of teaching hygiene in its schools." Dr. Sawers Scott acknowledged the work of the corporation in supplying good water, baths, and wash-houses, in widening the air space of houses, and in the matter of sewage disposal. But all these things were useless unless the people were taught the value of cleanliness and the danger of sleeping where the windows and means of ventilation were obstinately kept closed. The association had for many years tried lectures on hygiene, "but had not reached the right people." He was supported by Mr. Horsfall, by Dr. Hewitt (who spoke of the ignorance of young mothers as to the feeding of children), and by Dr. R. B. Wild, who called attention to the prevalence of ringworm and the increase of skin disease. Dr. Emrys Jones referred to the defective eyesight of many school-children leading to their being set down as stupid and being punished. He stated that the method adopted in Salford of testing the eyesight of the children had had good results. Dr. A. W. W. Lea said that in New York and other cities the daily medical inspection of the schools and scholars had resulted in a great diminution of measles, scarlet fever, diphtheria, and skin affections. The chairman thanked the deputation for the clear way in which various points had been put and said that "if the Board had been guilty of any oversight in the past it had been through want of fresh information." But surely it is the duty of school boards to seek information and not to wait the advent of deputations from such voluntary bodies as the Sanitary Association.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *Herefordshire Medical Association.*

THE annual meeting of this society was held at Hereford on Oct. 30th, Mr. H. Cecil Moore being in the chair. Dr. Gerald R. Leighton read a paper upon Snake-bite in England in the course of which he said that any case of snake-bite in this country which shows signs of venom symptoms if due to a British species must be the bite of an adder (*Vipera berus*). The bite almost always occurs from the person bitten being unaware of the proximity of the adder, which is doing its best to escape observation. The hand or the ankle is the part usually affected, as the bite generally occurs through the person picking up something off the ground near to the reptile or through treading on, or near, it. The resulting symptoms depend more upon the actual amount of venom injected than upon such circumstances as the heat of the day, or the state of health or the age of the patient. Death may result very rapidly from heart failure when the dose of venom is sufficiently large. In other cases the symptoms usually seen are pain at the seat of puncture and extending up the limb, with lymphangitis, symptoms of local and general blood-poisoning, vomiting, photophobia, and nervous symptoms. If the

patient survives three days recovery is usual. As the venom of the adder, unlike that of the cobra, does not pass through animal membrane, the wound may be sucked with impunity. There is no latent period in adder-bite as in cobra-poisoning, death being rapid and symptoms instantaneous in fatal cases. Dr. Leighton considers that in the absence of an antitoxin no definite treatment can be adopted beyond such as is suggested by the symptoms as they arise.

*West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health.*

At the annual meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health, held at Bristol on Oct. 31st, Dr. J. Howard-Jones of Newport was elected secretary. Mr. J. C. Heaven of Bristol, who has been secretary for the past seven years, is the president for the present year, and in his presidential address dealt with the question of Prevention of Disease, elaborating and emphasising the dictum of Professor Koch at the British Congress on Tuberculosis that it is a great blunder to treat pestilences uniformly. A large portion of the address was occupied in discussing the measures which should be taken in order to prevent the spread of diphtheria, and special attention was drawn to the necessity for the competent inspection of contacts who should have not only their throats but their nasal cavities examined for the purpose of ascertaining whether they are free from Klebs-Löffler bacilli. The frequency of nasal diphtheria without obvious symptoms is only now becoming recognised, and this lack of recognition is doubtless due to the absence in many districts of properly equipped public health laboratories. That the condition does exist is manifest from two instances related by Mr. Heaven. Owing to an outbreak of diphtheria in a Bristol school he examined the children in attendance and found among them 15 cases of diphtheria, 11 of which were nasal without constitutional symptoms, unrecognised and able to go about and to spread the disease freely. After the exclusion of the infected children from the school and its closure for the Easter holidays the outbreak ceased. In another school among 12 children examined, in seven of them bacilli were found in the nose only, in three in the throat only, and in two both in the throat and nose. Mr. Heaven is of opinion that the increase of diphtheria in towns and the failure to control its spread may be largely attributed to the non-recognition of the facts that diphtheria is capable of assuming every grade of severity, that it is the mild, unrecognised cases that are chiefly responsible for the spread of the disease, and that it is not by any means only in the throat that unrecognised cases occur. There are unfortunately many opportunities in other parts of the country for dealing with outbreaks of diphtheria upon the lines laid down by Mr. Heaven who is to be congratulated upon the energy and persistence which he has displayed to secure the isolation of "carriers" of the disease.

*Prevention of Consumption.*

It was stated in THE LANCET of Oct. 26th, p. 1160, that a sub-committee of the Bath Board of Guardians had been appointed to confer with the Bristol Guardians as to the practicability of the two boards jointly providing an institution for the treatment of phthisical patients. The result of the conference having been reported to the Bath board on Oct. 30th, it was decided not to combine with the Bristol board, but to treat the Bath patients in a building adjoining the workhouse, when it is estimated that if the average number of patients under treatment is 10 the cost per patient will be 13s. 3d. per week, or reduced to 11s. per week if the average number is 20. The Herefordshire Medical Association have appointed a sub-committee to consider the desirability of forming a branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis.

*Pontypridd Workhouse.*

Notwithstanding several communications from the Local Government Board and the recommendations of their own medical officer (Mr. Howard Davies) the Pontypridd Board of Guardians, which for Poor-law purposes has charge of a population of 204,000 persons, has for several years declined to provide an adequate staff of trained nurses in the workhouse infirmary. At the end of last September Mr. Davies reported upon the necessity for taking immediate steps to remedy this deficiency, and although attempts have since been made to postpone indefinitely a settlement of the question this has been prevented by the

persistence of the medical members of the board. There are on an average about 50 patients in the infirmary who are cared for by only one trained nurse. When the board decided recently to appoint a second nurse it was discovered that there were no quarters available for her accommodation. The medical officer then advised that the existing tramp wards should be removed and replaced by suitable nurses' quarters. The present accommodation for tramps could hardly be worse than it is, for every applicant has to go into the main entrance hall of the workhouse so that it is almost impossible to prevent contact with the inmates; indeed, upon three occasions in recent years small-pox has found its way from the tramp wards into the workhouse. The removal of the tramp wards from the precincts of the workhouse is therefore an urgent necessity, even if the site of the wards were not wanted, as it certainly is, for other and more suitable purposes.

*Epileptic Colony for Wales.*

In his recently issued annual report to the Local Government Board, Mr. F. T. Bircham, the general inspector for Wales and Monmouthshire, expresses the opinion that Wales would make a very good area for an epileptic colony and for an idiots school and he regrets that the county councils have not taken the matter up. The Glamorgan County Council had the subject under discussion a few years ago and issued a circular letter to the medical practitioners in the county with a view to ascertain how many non-pauper cases of idiocy and epilepsy there were in the county. It would appear that no effect was given to the result of this inquiry.

*South Wales and Monmouthshire Branch of the British Medical Association.*

At a meeting of the South Wales and Monmouthshire Branch of the British Medical Association held at Swansea on Oct. 25th, a committee was formed to take into consideration the readjustment of contract pay throughout the district. In connexion with certain articles which have recently appeared in the Cardiff daily newspapers the following motion was passed:

That in the opinion of this meeting it is highly inexpedient that signed articles discussing questions of professional treatment should appear in the lay press.

*New Nurses' Home at Salisbury Infirmary.*

The new nurses' home which has been erected at Salisbury as a local memorial of Her late Majesty's Diamond Jubilee was formally opened on Nov. 1st by the Marchioness of Lansdowne. The new building is in connexion with the Salisbury Infirmary and is named the "Victoria Home." The cost of erection and furnishing was £7800, the whole of which sum, with the exception of £200, has already been subscribed.

*Devon and Exeter Hospital.*

At the quarterly meeting of the governors of this institution held on Oct. 31st it was reported that for the corresponding quarter of 1900 there was a deficit of £1416, whereas at present there was a favourable balance of £730, in addition to which the sum of £3000 has been placed on deposit. This is the first time for many years that such a favourable state of affairs has occurred.

Nov. 5th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Bubonic Plague in Glasgow.*

SOME not unnatural alarm was caused in the city when on the morning of Nov. 1st it was officially announced that plague had reappeared in Glasgow. For some few days rumours had been current in reference to the suggestion that the outbreak in Liverpool had been traced to Glasgow, but on the last day of October an authoritative statement was issued contradicting this report. It now appears that on Oct. 19th a case of a suspicious nature was notified to the health authorities. A second case occurred on Oct. 20th and a third on Oct. 21st, each of the patients being a servant in the employ of the Central Station Hotel. All were removed to Belvidere Hospital and were kept in strict isolation, but it was not until a careful bacteriological investigation had been completed that they were definitely diagnosed as cases of plague. By this time a fourth servant in the

hotel had developed symptoms, and one of the original patients, a man, had died. On Nov. 1st a fifth case was recognised in the person of a barmaid at Airdrie Station whose duty it was to return to Glasgow every evening and who slept in the Central Station Hotel. All the patients have thus come from the same house. The hotel has been closed in order to facilitate a thorough examination, and some 200 employes remain in it under medical supervision. Some have been inoculated with anti-plague serum, and those whose work was more especially carried on in the basement have been removed to the corporation reception-house. To-day's report is that no further development has taken place, and that the patients in hospital are making favourable progress. The theory of the authorities is that the outbreak is probably to be traced to conveyance of the poison by means of rats. It is certain that rats have recently got into the basement of the hotel and that all the affected persons either worked or slept in the basement. A lively crusade against rats is, as a result, in active progress through the city. Dr. A. K. Chalmers has issued a memorandum on the subject, suggesting methods by which they may be exterminated or excluded from dwelling-houses, and these, as may be readily understood, are being energetically put into operation. Concerning the chance of the disease extending the authorities hold reassuring views. The strictly limited character of the outbreak, though a fortnight has now elapsed since the appearance of the first case, is of hopeful augury, and there is no small ground of comfort in the recollection of the success with which the much more threatening circumstances of last year were promptly controlled.

#### *University of Glasgow.*

A highly influential meeting in support of the movement for promoting the extension and better equipment of the University was held in Glasgow on Oct. 31st. The cordial feeling of mutual goodwill existing between "town and gown" was illustrated by the presence of the Lord Provost in the chair and by the numerous representative citizens and academic dons who occupied places on the platform. Letters expressing sympathy with the object of the meeting were read from Mr. A. J. Balfour, M.P., Mr. Joseph Chamberlain, M.P. (both former Lord Rectors of the University), Lord Balfour of Burleigh, and Sir Henry Craik, K.C.B. The speakers included the Earl of Elgin, Lord Reay, the Right Honourable James A. Campbell, M.P., the Solicitor-General for Scotland, Principal Story, and Professor J. G. McKendrick. Principal Story gave a general account of the objects and present position of the movement. He recalled the fact that the University had been able in recent years to provide new and highly efficient laboratory and museum accommodation for the departments of botany, engineering, pathology, and anatomy. In these respects the University is now well abreast of the claims of the present day, but in other directions much remains to be done, and it is hoped that a sum of £150,000 will be raised. Towards this total £60,000 have already been received. Principal Story expressed an eloquent appreciation of Mr. Carnegie's unparalleled benefaction, but insisted that the need for further financial assistance still remained if the Scottish universities were to continue to hold their own in the educational world, and on this point he received repeated support from the other speakers. A sketch of the proposed developments in connexion with the medical school was presented by Professor McKendrick. It is hoped to provide for the teaching of physics a new laboratory which may compare with the botanical institute recently erected at a cost of £18,000 and the new anatomical rooms which have cost £13,000. In chemistry further laboratory accommodation is required to meet the growing numbers of medical and science students, and it is proposed also to endow a chair of organic chemistry. The claims of physiology, materia medica, and public health are to be met by the erection of a new building which, with the necessary new equipment, will cost about £40,000. When this is accomplished there will be room in the present buildings for the expansion of other departments, a special surgical laboratory costing some £10,000 being now in course of erection. Professor McKendrick advocated the building of a new maternity hospital, the provision of teaching museums, and the development of fellowships for the prosecution of research. The meeting altogether was very enthusiastic and the University authorities are to be congratulated upon the skill with which they have managed to associate all interests in a common determination to

maintain the well-founded reputation of their *alma mater*.—The half-yearly meeting of the General Council of the University was held on Oct. 30th. Sir John N. Cuthbertson and Mr. W. R. Copland were re-elected assessors on the University Court. The meeting was a very long one and in the end the very unusual course was adopted of adjourning the council until Nov. 6th. A considerable amount of time was occupied in the discussion of the proposed re-arrangement of the academic year and the decision of the council was in favour of the establishment of a summer session for the arts faculty. The council recorded its grateful appreciation of Mr. Carnegie's gift and its sympathy with the movement for securing the better equipment of the University. In memory of the late Professor Dickson a valuable collection of theological works has been presented to the University library, in the service of which the late professor was engaged for nearly 40 years. A portrait of the late Principal Caird has been added to the gallery of the Divinity Hall, having been presented for this purpose by Mrs. Caird.

#### *Faculty of Physicians and Surgeons of Glasgow.*

At the annual meeting of the Faculty for the election of office-bearers held on Nov. 4th, Dr. James Finlayson was re-elected President and Mr. John Burns visitor. Dr. James D. Maclaren retired from the office of treasurer, which he has held for more than a quarter of a century, and his place was filled by Dr. William L. Reid. For the vacant examinations there were several contests, the new examiners being Mr. Thomas Gray, D.Sc., B.Sc. Lond., in Chemistry, Dr. A. K. Chalmers, medical officer of health, Dr. Hugh Galt, and Dr. R. M. Buchanan in various departments of Public Health. In Anatomy the out-going Dr. Thomas H. Bryce succeeded in securing his re-election.

#### *Glasgow Ophthalmic Institution.*

A course of post-graduate lectures on Diseases and Injuries of the Eye was inaugurated on Tuesday evening last under the presidency of Professor John Glaister. There was a good attendance, over 40 general practitioners being present. In addition to a presentation of clinical cases and a display of stereoscopic photographs, Dr. Ramsay gave a lantern demonstration on Conjunctivitis, special reference being made to the microbic origin of its various forms and their treatment.

Nov. 6th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *The Inaugural Address of the Royal College of Surgeons in Ireland.*

THE President of the Royal College of Surgeons in Ireland, Dr. Thomas Myles, delivered the inaugural address to the students on Nov. 2nd in the anatomical theatre of the College. There was a large attendance of visitors and students, and the lecture proved of much interest. Dr. Myles has long made the position of the men who join the Army Medical Service a matter of study so that his opinion on the inducements held out by that service to young men carries much weight. He adopted the somewhat novel attitude nowadays of congratulating Mr. Brodrick, the Secretary of State for War and of praising him for his recent efforts in connexion with Army medical reform. Speaking for the College and for himself, he said that he was sure that he would win the sympathy of all when he said that they were sincerely thankful to Mr. Brodrick for the great effort which he had made to improve the conditions of service in the Royal Army Medical Department. He alluded to the three blemishes of the scheme which he had already pointed out in a letter to the *Times*, and suggested that they could be removed without interfering with the general efficacy of the whole. Dr. Myles was plainly of opinion that the Army Medical Service will soon offer a fair career to the young surgeons of Ireland. As to the Poor-law Medical Service in Ireland to which so many students aspire, Dr. Myles was very outspoken. "The whole Irish Poor-law Service is," he said, "one to be shunned, and I cannot conceive how self-respecting men can offer themselves for vacancies in such numbers as they do."

#### *Royal Academy of Medicine in Ireland.*

The annual general meeting of the Royal Academy of Medicine in Ireland was held at the Royal College of

Physicians of Ireland on Oct. 25th, when the report of the last session was adopted and the officers for the coming session were elected. It was announced to the meeting that invitations had been received to the first Egyptian Congress of Medicine to be held at Cairo in December, 1902, and to the Fourteenth International Congress to be held in Madrid in April, 1903. Dr. Lombe Atthill was elected President for the year 1901-1902. Sir Christopher Nixon as President of the Royal College of Physicians of Ireland and Dr. Thomas Myles as President of the Royal College of Surgeons in Ireland, will fill the positions of President of the Medical Section and President of the Surgical Section respectively.

#### *Precautions against the Bubonic Plague in Dublin.*

A joint meeting of the Port Sanitary Authority and the Public Health Committee was held on Nov. 4th, to consider what precautions should be taken in order to prevent the entry of the plague to Dublin. Mr. Edgar Flinn, medical inspector of the Local Government Board for Ireland, attended, and took part in the discussion. It was considered by Sir Charles Cameron, the port medical officer of health, that although the existence of the plague in Glasgow and Liverpool rendered possible its transmission to Dublin by ships coming from those cities the probability was a remote one. It was resolved, however, that a medical inspection of the vessels coming from those ports should be commenced forthwith, and that circulars dealing with the necessary precautions against plague, more especially as regards the destruction of rats, should be sent out. The Public Health Committee have the Dublin port hospital ship available if it should be required.

#### *The Annual Dinner of the Cork Medical Association.*

On Saturday last the members of the above association held their annual dinner at the Imperial Hotel. Dr. T. Atkins presided. The toast of "The Cork Medical School" was responded to by Professor Charles and Professor Hartog. The former, in the course of his speech, mentioned that a grave peril might be threatening the Cork College, as there were grounds for believing that Mr. Horace Plunkett, Vice-President of the Agricultural and Technical Department, was endeavouring to have the Cork and Galway Colleges converted into technical colleges to be utilised in connexion with his department. Professor Charles dwelt on the subject at length and was listened to with great attention. The next toast was "The Navy and Army," which was responded to by Colonel Macnamara, principal medical officer, and Staff-Surgeon J. Moore, H.M.S. *Black Prince*.

#### *Proposed Nurses' Home at the Belfast Union Infirmary.*

The question of a new nurses' home at the Union Infirmary, Belfast, has been referred back for further consideration. It will probably cost £11,000; and those who object to its going on at present do so on the ground that the extension of the infirmary will cost from £4000 to £5000, the erection of a central laundry £6000, the addition to the fever hospital £1000, and that the fever cases have fallen in numbers. Those in favour of the scheme say that the nurses have not proper accommodation and that owing to this several have been laid up with typhoid fever, and that it was a curious fact that the very people on the board of guardians, who objected to the new nurses' home on the ground that there was enough work on hand, were urging them to spend a sum of £13,500 on a new board-room (which the Local Government Board said had as much space as the House of Commons) and offices.

#### *The Poor-law System in Ireland.*

There are many people in Ireland who will sympathise strongly with the following resolution which has been passed by the Larnie Board of Guardians:—

That this board is of opinion that the Poor-law system is a very costly one, giving no adequate return for the money, time, and labour expended on it; that it tends to encourage and foster idleness, thriftlessness, drunkenness, and immorality, and provides no means for dealing effectively with the tramp nuisance, but tends to encourage and perpetuate it. We, therefore, call upon the county council, the Members of Parliament for the county, and the Irish Local Government Board to use their influence with, and if necessary, to bring pressure to bear on, the Government with a view to having such a measure of reform passed as will remedy the existing evils and bring it into line with the present condition and needs of the country.

A Poor-law conference is to be held in Belfast on Nov. 7th and 8th. The following subjects are to be discussed: The Treatment of Imbeciles and Epileptics; Vagrants and Able-bodied Paupers; Children Born out of Wedlock, the

Liability of their Fathers for their Maintenance; Nursing in Infirmarys; and Boarding-out of Children.

#### *The Nursing Question in Lurgan Workhouse.*

The authorities of Lurgan Workhouse, being anxious to adapt themselves to the changes required by the Local Government Board so that their infirmary might be qualified for the training of probationer nurses whose professional status would be recognised by the central authority, have ascertained that the Local Government Board were ready to sanction the appointment of a resident medical officer (male or female) who, subject to the senior medical officer (Dr. J. S. Darling), would have control of the sick wards, the nurses, and the nursing arrangements. They would also sanction a staff of four charge nurses, four assistant nurses (qualified), and such probationer nurses as might be employed on the recommendation of the medical officer. This staff would do for the infirmary, a charge nurse and an assistant nurse being requisite for the fever hospital. If a resident medical officer is appointed and a training scheme submitted the Local Government Board have agreed to approve of the training of probationers. A special meeting to deal with the matter has been convened.

#### *The late W. H. Caldwell, M.D. R.U.I., J.P.*

It is with regret that I announce the death of Dr. W. H. Caldwell, coroner for Coleraine and district, which took place at his residence in that town on Oct. 25th after an illness of three months' duration from paralysis due to cerebral disease. Early in life Dr. Caldwell was a pharmaceutical chemist, but he subsequently studied medicine at Queen's College, Belfast, and graduated M.D. of the Royal University of Ireland in 1880. Practising in Coleraine he was in 1883 elected coroner for that district and he was a member of the board of guardians and a justice of the peace for county Londonderry. His death is greatly regretted by a numerous *clientèle* and he leaves a widow and three young children to deplore his death. He was buried in Coleraine Cemetery on Oct. 28th, the immense concourse of persons who were present testifying to his extreme popularity.

(FROM OUR OWN CORRESPONDENT.)

#### *Treatment of Lupus by Potassium Permanganate.*

At the meeting of the Academy of Medicine held on Oct. 22nd M. Hallopeau read a paper dealing with some researches of Dr. Butte on the treatment of lupus by potassium permanganate. Dr. Butte uses compresses soaked in a 2 per cent. solution of permanganate, by which he states that he has made a number of cures. M. Hallopeau tried the method in 25 cases and came to the conclusion that ulcerated patches of lupus heal with great regularity after some weeks or months, according to their extent. On non-ulcerated patches the treatment, as a rule, is without effect. The permanganate acts with greater rapidity than any other method as long as it is used in cases which are too extensive to be amenable to phototherapy. This latter method is the only one capable of producing a good effect in cases where there are no ulcerations or prominent tubercles, but where there are simply induration of the skin and deep-seated miliary nodules. M. Hallopeau referred in addition to a method of treatment promulgated by M. Kaczanowsky which consists in applying for a quarter of an hour a layer of potassium permanganate. A scab-forms which falls off at the end of three or four days, leaving a clean wound which rapidly cicatrises. This treatment is successful in superficial cases, but has no effect on deep-seated tubercles.

#### *Foundation of a Medical School at Hanoi.*

M. Doumer, the Governor of Indo-China, has decided on the foundation of a school of local medicine at Hanoi to which is to be annexed a hospital. The object of this school is to rear up a race of native Tonkinese medical men who are to be trained under French practitioners, both military and civil. Two years ago General Galliéni started a like institution in Madagascar. The average French practitioner is not in love with these schemes, for he considers that they take away outlets for the relief of a profession which is overcrowded at home, especially in Paris. They should remember, however, that very few

practitioners ever dream of going to the colonies, and that nearly all the colonial civilian practitioners are retired military or naval surgeons who have sent in their papers in order to settle in the country. On the other hand, the Governor-General cannot be expected—merely out of consideration for the metropolitan practitioners who do not choose to go to the colonies—to deprive himself of so powerful a civilising agent (one, moreover, who will approximate to European civilisation) as the native medical man.

#### *Infantile Mortality in France.*

Infantile mortality in France still keeps at a high level. Although popular notions of hygiene are more wide-spread than they were, and although the mortality-rate is certainly sinking, yet the figure reaches the enormous total of 167 per 1000. Only too often the newly-born infant among the lower classes dies solely on account of the ignorance of hygienic conditions displayed by its parents. The infant may be nursed by its mother or bottle-fed, but only too soon it is given food quite unfitting for its years and nothing is more common in the out-patient rooms at hospitals than to see mothers bringing wasted babies who, they say with pride in answer to questions, are fed on "just what we have ourselves." The same thing occurs in country districts where with a view to strengthen the child they give it brandy or absinthe in its milk. These very mothers, however, when they are instructed by the physician at the hospital pay the greatest attention to what he says and often bring up their children admirably. Maternal ignorance is therefore what has to be combated and with this end in view an active propaganda has been set on foot. The Municipal Council of Paris, on the motion of Dr. Cazalis, has just decided that whenever the birth of a child is registered in any *mairie* there shall be sent to the mother a short paper containing directions as to the chief points in the feeding and bringing up of an infant. Professor Budin and Dr. Variot, members of the sub-committee on *orphanes*, have been appointed to draw up the paper in question, and it is earnestly to be hoped that the movement may not be confined to Paris but may be extended to every *mairie* in France.

#### *Lead-poisoning from the Use of a Pewter Mug.*

At the meeting of the Hospitals Medical Society held on Oct. 25th M. Variot reported the case of a child who exhibited Complete Paralysis of the Lower Extremities and Paresis of the Upper Limbs but without any Sphincter Trouble. The little patient also had a very marked lead-line on the gums. The case was evidently one of lead-poisoning, and the only cause for which that could be ascertained was the use by the child of a mug made of pewter containing a large proportion (75 per cent.) of lead. All the symptoms which the child exhibited could be attributed to the ingestion of lead owing to small portions of the metal being dissolved by the liquids, more or less acid, which were drunk from the mug. The child was at the time of the meeting nearly well, although the extensor muscles were still rather weaker than the flexors. M. Variot drew the attention of the meeting to the fact that in certain children's hospitals mugs were still used made of pewter containing a very appreciable quantity of lead (12 per cent.) and that their constant use might easily be most harmful. M. Rendu remarked that he had seen a case of cerebral disease due to lead-poisoning in a man who was in the habit of drinking cider which had been kept in pewter.

### SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

#### *Tumours of the Stomach from a Medical and Surgical Point of View.*

THIS subject was discussed at length at the annual autumn meeting of Swiss medical men at Olten on Oct. 25th.—Dr. Huber of Zürich gave a *résumé* of 57 cases which he had given over into the surgeons' hands—for operation 34 cases of cancer and 23 cases of gastric ulcer or its consequences (benign tumours). In the 34 cases of carcinoma gastrostomy was performed nine times with one casualty and gastro-enterostomy in 25 cases (20 men and five women) with six deaths. The presence of the following symptoms—viz., motor insufficiency of the stomach (100 per cent.), absence of muriatic acid (76 per cent.),

and presence of lactic acid (70 per cent.)—generally decides the diagnosis, which in each case was verified by the surgeon. The rare occurrence of vomiting was remarkable (only five cases). Half the patients were between the ages of 30 and 50 years and the ages of the other half ranged between 50 and 70 years. They had generally shown gastric symptoms for half a year or more prior to the operation. In 26 cases a tumour could be palpated; the other nine cases, however, proved to be rather more advanced than these, so that a very early diagnosis was often impossible. The 23 cases of ulcer and its consequences all had motor insufficiency of the stomach in a very severe degree and some patients were very emaciated. Dr. Huber recommended these cases for operation after regular treatment with lavage for six or eight weeks has not alleviated the symptoms, thus appealing to the surgeons, "Cure our patients!"—Professor Krönlein of Zürich, who had operated upon most of Dr. Huber's patients, spoke from a surgical point of view, and he thoroughly agreed with Dr. Huber's indications for operation. He had collected the reports of 744 consecutive cases operated upon by Rhydigier, Billroth, Czerny, Mikulicz, Kocher, Roux, and himself (156) in the last 20 years. The mortality when carcinoma was present was 39 per cent. where gastrostomy was performed and 30 per cent. where the palliative operation of gastro-enterostomy was performed, whereas in the case of benign tumours the mortality in 102 cases amounted to only 19.6 per cent. But it must be considered that with increasing experience the operative result was continually improving; his own operations showed a total mortality of only 25 per cent. for cancer and 15 per cent. for benign tumours. In a minority of cases a radical cure was obtained, but the majority of the patients generally succumbed after living for a year or two.—Professor Kocher of Bern wished the total of radical operations to increase and the numbers of the palliative operations to decrease. He was all the more of this opinion as patients on whom gastro-enterostomy had been performed often lived for several years in apparently good health. Whereas the mortality of all his cases was 29 per cent., the results were improving rapidly in latter years. Of the last 52 cases he only lost 15 per cent., of the last 22 cases only 5½ per cent.; these figures refer only to carcinoma. Out of 60 patients operated upon for ulcer and benign tumours he only had five deaths, and could therefore sincerely recommend the physician to trust such patients to the surgeon's knife. After-examination of the stomach proved that the muscular and chemical forces returned and the digestive powers became normal.

### ROME.

(FROM OUR OWN CORRESPONDENT.)

#### *Disappearance of Plague at Naples.*

No fresh cases of plague have been reported from Naples or its neighbourhood for a fortnight. All the patients having now recovered and the persons under observation having been set at liberty the issue of bulletins from Nisida has stopped. The disease has thus been stamped out in the remarkably short space of 14 days, reckoning from the notification of the first till the isolation of the last case. Whatever blame the authorities may have incurred in the first instance they cannot be reproached for lack of promptitude or energy in dealing with the outbreak once its true nature was recognised. The result is a veritable triumph for the science of modern sanitation and at the same time an immense material saving to the city, and especially to the commerce of Naples.

#### *The Second Italian Congress of Pediatrics.*

Amongst the subjects discussed at the Pediatric Congress which has just concluded its labours at Florence was that of the respective merits of sterilised and of ordinary unboiled milk in the artificial feeding of infants. The general opinion, as summed up by Professor Mya, seemed to be that the milk should be sterilised, notwithstanding the difficulty of obtaining a really aseptic product and the generally admitted deterioration of its nutrient qualities during the process of sterilisation. Until we invent some practical method of taking the milk from the cow antiseptically and of preserving it in an aseptic condition—which would no doubt be the ideal plan—we should continue our present precautions and avoid the many risks attending the use of milk in its raw

state. Another of the questions dealt with by the Congress was the canteen system in elementary schools, in regard to which the following resolution was passed:—

Considering (1) that the intellectual benefit derived from school is smallest, and the physical damage done greatest, when the children attend in a fasting condition or insufficiently fed; (2) that the nourishment supplied at school age should be adapted not only to the organic *status quo* but also to the development of the body and to the repair of the losses ensuing from the often excessive mental work; and (3) that in infancy the future of the individual is decided, and that the most efficient means of preventing disease and of rendering the new generation robust lies in the possession of good health and especially of a healthy stomach: for these reasons the Congress recommends that the Government municipalities, public institutions, and private charities should organise the providing of refectories for the children in elementary schools; and it is further of opinion that in order to render efficient this hygienic measure, so necessary to social welfare and education, the quality and quantity of the daily rations should be determined scientifically.

#### *Report on the Plague at Naples.*

The report of the commission appointed to inquire into the facts connected with the outbreak of plague at Naples has been published. The object of the inquiry was to ascertain with whom the responsibility rested for the importation of the disease and the delay in notifying it and if possible to discover in what way the infection was introduced into the city. The result fully confirms the impression which has long been prevalent—namely, that gross carelessness, if nothing worse, has marked the conduct of the sanitary service of Naples and especially of the port. In coming to a decision the commission had to consider separately the responsibility (1) of the medical man who first denounced the cases; (2) of the local administration at the Punte Franco; (3) of the medical men who attended the patients first attacked; and (4) of the maritime sanitary officials. To Dr. Sorge, who originally drew attention to the suspicious cases, no blame for delay can be attached, since his only duty at the Punte Franco was to attend to accidents among the dock-labourers. In regard to the local administration, it appears that owing to the buildings at that spot being devoted entirely to the storage of imported merchandise there was no sanitary supervision exercised either by the Government or by the municipality, but only a fiscal control for the levying of customs dues. There was therefore no sanitary officer whose special duty it was to attend to the workpeople there and any sick person among them had to seek medical advice elsewhere. As to the different medical men—general practitioners and hospital surgeons—who attended the earlier cases and diagnosed them variously as adenitis, typhoid fever, typhilitis, pneumonia, &c., no suspicion of the real character of the malady seems to have arisen in their minds; and therefore, although they are perhaps blameable for their failure in diagnosis, they can scarcely be held guilty of a breach of the law, a contravention of which presupposes a recognition, or at least a suspicion, of the true nature of the disease. With respect to the responsibility of the maritime sanitary officials, the inquiry resolved itself into an examination, in the first place, of the special cases to which the outbreak of plague has drawn attention, where suspected ships had obtained *libera prateria*; and, in the second place, of the working of the sanitary service of the port previously to the outbreak under normal conditions. The commissioners find that there is no proof of any of the ships having had a case of plague on board, but, on the other hand, they severely censure the authorities for the way in which the sanitary measures prescribed by law had been carried out. They comment upon the absence of the officials from their posts when their services were required, on the perfunctory character of the medical visits to the incoming ships, and on the absurdly inadequate nature of the measures for disinfection, which they characterise as a mere farce. It appears that the medical visit was confined to the crew and the steerage passengers, and consisted in a rapid and general review of them without any questions being asked which might elicit the existence of individual ailments. The disinfection of personal effects in cases where such diseases as typhoid fever, diphtheria, &c., existed was left to the sanitary police, who carried it out in a totally inadequate manner without any supervision from the medical officer, who meanwhile passed his time chatting with the ship's officers in the saloon, frequently joining them also at their mess. Under such conditions it is impossible to determine how, or by which ship, the infection was imported, but it was sufficiently clear that while, in the concluding words of the report, "the prophylactic measures sanctioned by the maritime sanitary law and other ordinances in force are

amply sufficient, the irregular, negligent, and incomplete execution of these—in other words the failure of the maritime sanitary officials to conscientiously discharge their duty—may have been, and perhaps really was, the actual cause of the calamity which has befallen Naples." As a result of the investigation the medical officers concerned have been called upon to exculpate themselves and have meanwhile been suspended from their duties at the port. The punishment awaiting these delinquents will, no doubt, be well deserved, but it is to be feared that they are merely the scapegoats and that the causes of all this negligence and mismanagement lie deeper—namely, in the generally effete and corrupt administration of the public affairs of Naples, which has been only partially exposed by the startling disclosures contained in the recently published report of the Saredo Commission.

#### *Intravenous Injections of Corrosive Sublimate in Foot-and-Mouth Disease.*

In his inaugural address to the Eleventh Italian Medical Congress which began its sittings at Pisa on Oct. 27th Professor Baccelli occupied himself chiefly with his new method of treatment for foot-and-mouth disease in cattle. He related how, on his appointment some months ago to the Ministry of Agriculture, he had found that Italy was suffering from a severe visitation of epizootic apthæ, and the idea had occurred to him that intravenous injections of a parasiticide might have beneficial effects in this as in other diseases. He recalled how, 12 years ago, he had employed with astonishing results intravenous injections of hydrochlorate of quinine in pernicious malaria, and later, also with success, similar injections of carbolic acid for tetanus, and he determined to make a trial of corrosive sublimate in foot-and-mouth disease. Happening soon afterwards to be at Civita Vecchia and aware that there were cases in that neighbourhood he instructed the municipal veterinary surgeon, Dr. Croce, how to apply the method, advising for young animals doses of from two to four centigrammes (from one-third to two-thirds of a grain) in each injection, according to the case; for adult animals from four to six centigrammes (from two-thirds to one grain); and for bulls from six to eight centigrammes (from one to one and a quarter grains); the solution containing for every centigramme of sublimate 75 milligrammes of chloride of sodium. The number of diseased animals so injected was 52, and all were rapidly and completely cured. Shortly afterwards he sent Dr. Croce to Sardinia where the disease had affected 26 animals. All of these were treated similarly and cured in the same speedy and thorough way. In other parts of Italy identical results were obtained by another veterinary surgeon, Dr. Cosea. Veterinary surgeons in general were doubtful about the safety of mercurial preparations in cattle and were almost averse to it, but these experiments proved that this idea was merely a prejudice, the fact being that cattle were singularly tolerant of mercury, which, moreover, was peculiarly well adapted for the treatment of apthæ, passing as it did directly to the chief seat of the disease—namely, the mouth—where it could be demonstrated in the saliva after the lapse of only one minute. Inquiries made by Professor Baccelli in regard to other methods of cure practised in Italy and elsewhere for foot-and-mouth disease showed that his mode of treatment was the best, and he was convinced that it would be the means of effecting an enormous pecuniary saving to the country. At its final sitting on Oct. 31st the Congress resolved to make the subject of "Intravenous Therapeutics" the leading theme of its next meeting, which will be held at Rome.

Nov. 2nd.

## NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

#### *Medical Practice in New Zealand.*

OPPORTUNITIES have during the recent Royal visit presented themselves by which I have been able to discover the opinions of several journalists and others associated with the *Ophir's* glorious visit to New Zealand in connexion with our general position "down under." It appears that three points in particular have struck those "from above"—our buildings, our municipal management, and our journalism. Now, the four careers for which the universities and other examining bodies at home can qualify a man are

those of the cleric, the medical man, the barrister, and the journalist. The Royal visitors, I imagine, saw but little of the first; happily (equipped as they were in the possession of (Dr. Manby) had little need of the second; owing to general rejoicing no necessity for the third; and the fourth estate was the only quarter from which they could form an opinion as to the literary attainments of the *hoi polloi* for which it caters. It is nevertheless an undoubted fact that all these professions are at the present moment, without exception, overdone in New Zealand. The legal profession, perhaps, first and the medical a good second. As a matter of fact successful tradesfolk in this colony endeavour to educate their sons that they may enter one of the above professions. Now, ever since the days of John Knox it has been possible for the child to obtain an excellent education in Scotland, and the boy who had the talent had barely to think about ways and means. The same holds good in this colony. The time is rapidly coming in New Zealand (as it has long ago come at home) when well-educated men, whose education has unfitted them for the real battle of life, can find no place "within the meaning of the Act." Many of these unfortunates would have been much happier if they had been left to the manual arts of their predecessors, and had not been (by too ambitious parents) beguiled by the gifts of a superior education to strive for positions beyond their reach. All the world over—and New Zealand is no exception—the tendency is to crowd into cities, and to seek gain from work which is not reproductive; to over-educate a colony must lead many of its units into heartburnings. Young medical men without family ties which bind them to the motherland and who meditate practising in some other clime, may have had their attention directed to the "Britain of the South"; to such the following particulars about New Zealand from a medical point of view may be of some interest. Many young medical men have arrived in this colony brimful of hope that a lucrative practice was readily obtainable. Let me again warn them, that, unless they go out with a sufficient stock of worldly goods to commence with, New Zealand is no longer the Elysium it once was. Competition for public appointments is remarkably keen, and "influence" is an important factor in obtaining them. As a rule higher fees are paid to general practitioners out here than in England, much higher as far as actual money is concerned; but, on the other hand, living, clothing, and the maintenance of house and servants—the last-named being very expensive luxuries—soon dispel the rosy hue which the fees may offer to those who are eking out an existence in Great Britain. The average fee paid to a general practitioner is 7s. 6d. per visit; midwifery fees range from three to five guineas or more, according to the status of the patient and to mileage; here, perhaps, the advantage ceases. Operative work is not as a rule generously responded to in the way of remuneration. The majority of the people are of the labouring or middle classes, who are struggling themselves to make both ends meet. These for the most part resort to the hospitals where skilled medical care and nursing can be obtained at a small weekly charge. In the larger hospitals the medical staff is honorary; in the smaller, where there is no competition, the medical officers receive a small salary. The better class of patients avail themselves of private hospitals which are becoming more and more numerous in the larger centres; some of these are simply nursing homes where people from country districts remote from medical aid can come to be confined, or to receive other medical assistance; others are practically run by operating surgeons for their own benefit, and here, to quote from Dr. Goodhart's recent admirable address in Medicine at the annual meeting of the British Medical Association, "people undergo serious operations for the purpose of stitching harmless mobilities—for it is only quite exceptional that it is otherwise—into their places." Here also "throats and noses suffer terribly from this lust of operation that has beset the public." The multiplication of these private hospitals has given a great impetus to operative surgery; there is a real danger that the best interests of the patient may be subordinated to the eagerness to devise an operative remedy. The majority of the thrifty members of the community belong to "clubs," and as there is no wage-limit many who joined a lodge during hard times but who have afterwards become affluent belong to them. Clubs are being more and more abused by well-to-do people. Every man finds his own level in the colonies much sooner—acting by himself and without influential aid—than he does in the old country. The men who succeed best are those with a good all-round knowledge of their profession and who have made some study of the "special departments."

A man, especially in the smaller townships, has to rely upon himself in many trying emergencies, and never knows when he may be called upon to perform any operation. The cost of bringing a consultant from another town is nearly prohibitive to people with moderate incomes, and most incomes are moderate. I may again remind intending medical emigrants that there is a medical school in New Zealand where students are annually presented after examination with their diplomas. Most of these diplomates do not commence practice until they have gone home for further study; Edinburgh seems to have a great attraction for many of them, and Edinburgh graduates form a large and influential contingent of the general body of medical men who practise in the colony. These Otago University students are well grounded before they go home to complete their medical education, and they omit no opportunity of attaining practical knowledge; when they return to New Zealand to commence practice they not only do themselves great credit, but reflect the same on their *alma mater*. A general practitioner, particularly if he has passed his first youth, coming out from the old country to practise in New Zealand will find the competition of these young colonials, enjoying local popularity and prestige, a very formidable one. Youthfulness, from a professional point of view is no disadvantage, and a professional career terminates earlier in life than is the case in England. The native population (Maoris) with few exceptions are now greatly impoverished, notwithstanding that the Government has by wise and generous legislation sought to protect them from themselves and from land-grabbers. Work amongst the natives is not usually much coveted; they are very fickle, will only carry out such instructions as fall in with their own ideas, and have a foolish prejudice against paying a medical practitioner's bill. Recently the Government has paid considerable attention to matters pertaining to public health; the work is yet in its infancy, but at no distant date there will be a regularly organised public health service, and there may be openings for men who possess special qualifications for this work.

#### *Birth- and Death-rates.*

The birth-rate in the colony for the year 1899 was 25.12 per 1000 persons living. The rate is lower than for the preceding year and, indeed, since the year 1881 there has been a steady decline. Indeed, notwithstanding the fact that the number of marriages solemnised has increased of late years the birth-rate for last year was the lowest so far recorded in the statistics of the colony. New Zealand had in 1880 the highest birth-rate of all the Australasian colonies—viz., 40.18 per 1000—but now the case is reversed, for the "Britain of the South" is at the bottom of the list with only 25.12. New Zealand shows the lowest death-rate as compared with the other Australasian colonies and, indeed, in European countries, being equivalent to 10.24 in every 1000 persons living. Deaths from violence in 1899 formed a large item in the total mortality, for the proportion per 10,000 persons living was 7.23, the total number of deaths having been 542, of which number 71 persons committed suicide. On the census being taken this year (April, 1901) it was discovered that the total population of New Zealand (exclusive of natives) amounted to 772,455. The native population is roughly estimated at 42,500, thus showing an increase in the population in both races since the census of 1896. Now, the number of medical practitioners in a young colony is sure to be of a more or less fluctuating character, various attractions drawing them here and there. At the present time the New Zealand Branch of the British Medical Association has enrolled 270 members, while on the register of the Colony no less than 664 names are to be found. Irregular practitioners, including several Chinese "doctors," herbalists, and medical galvanists, play their part here as elsewhere in Australasia.

Sept. 26th.

UNIVERSITY OF CAMBRIDGE.—The University Lectureship in Medicine will be vacant at Christmas by the resignation of Dr. D. MacAlister.—The Examiners for Medical Degrees in the current academical year are—in Physics, Mr. Wilson, F.R.S., and Mr. Skinner; in Chemistry, Mr. Adie and Mr. Morrell; in Elementary Biology, Mr. Bateson, F.R.S., and Mr. Blackman; in Human Anatomy, Professor A. Macalister, F.R.S., and Professor Birmingham; in Physiology, Mr. Lloyd Tuckett and Mr. Waymouth Reid, F.R.S.; and in Pharmaceutical Chemistry, Mr. Ivatt and Mr. Purvis.—On Oct. 24th the following degrees were conferred: M.D., G. F. McCleary, Trinity Hall; M.B., J. A. Glover, St. John's.

## Medical News.

**NATIONAL DENTAL HOSPITAL.**—The annual distribution of prizes at the school connected with this hospital, of which H.R.H. the Duke of Cornwall and York is President, took place on Oct. 24th. The following is a list of awards. Dental Anatomy: medal, Mr. W. H. Haskew; certificate, Mr. S. Wheeler. Dental Mechanics, Theoretical: medal, Mr. F. P. Hamilton; certificates, Mr. W. H. Haskew and Mr. A. Allshorn. Dental Mechanics, Practical: medal, Mr. W. H. Haskew; certificate, Mr. W. Mountain. Dental Metallurgy: medals, Mr. H. G. Elstob and Mr. W. H. Haskew; certificate, Mr. F. P. Hamilton. Dental Surgery: medal, Mr. F. P. Hamilton; certificates, Mr. W. H. Haskew and Mr. F. A. Howorth. Operative Dental Surgery: medal, Mr. F. P. Hamilton; certificates, Mr. H. G. Elstob and Mr. L. Mosely. Dental Histology: medal, Mr. W. H. Haskew. Ash Prize: Mr. F. P. Hamilton. Rymer Gold Medal: Mr. W. H. Haskew. The Dean, Mr. Sidney Spokes, in alluding to the satisfactory condition of the school, mentioned that Mr. Hugh Candy had been appointed lecturer on Dental Metallurgy and Mr. Kenneth Goadby lecturer on Dental Bacteriology. Dr. G. Vivian Poore, after distributing the medals and certificates, delivered a brief address, to which reference has been made in a leading article contained in THE LANCET of Nov. 2nd, p. 1206.

**VACCINATION IN LEICESTER.**—The annual report of the medical officer of health of the borough of Leicester, just issued, shows that during the year 1900 there was a material increase in the number of people vaccinated, the total being more than double that of the previous year and nearly four times that of 1898. The following statistics show the private and public vaccinations in the borough of Leicester for the past 16 years:—1885, 979 public and 863 private, total, 1842; 1886, 561 public and 561 private, total, 1122; 1887, 188 public and 286 private, total 474; 1888, 80 public and 234 private, total 314; 1889, 31 public and 141 private, total 172; 1890, 12 public and 119 private, total 131; 1891, 6 public and 86 private, total 92; 1892, 12 public and 121 private, total 133; 1893, 44 public and 205 private, total 249; 1894, 29 public and 104 private, total, 133; 1895, 12 public and 63 private, total, 75; 1896, 19 public and 67 private, total 86; 1897, 11 public and 70 private, total 81; 1898, 12 public and 80 private, total 92; 1899, 56 public and 100 private, total 156; 1900, 155 public and 188 private, total 343.

**UNIVERSITY COLLEGE, BRISTOL.**—The following prizes were awarded in the medical department on Oct. 25th. Summer session:—Pathology, prize, J. Crétin. Medical Jurisprudence, certificate, C. Corfield. Operative Surgery, prize, C. Corfield. Midwifery, prize, A. Short. Practical Medicine, Surgery, and Midwifery, certificates, W. Webb and A. Short. Practical Physiology, prize, W. H. J. Pinniger; certificates, W. Ring, R. Bodman, C. E. K. Herapath, F. Perry, W. Lennox, H. Goodden, R. Vaughan, and F. G. Bergen. Pharmacology, prize, S. Hayman; certificate, T. Pratt. Materia Medica, prizes, F. G. Bergin and W. Pinniger. Practical Chemistry, prizes, C. Plumley and W. King; certificates, R. Lecky, R. Vaughan, and G. H. Smith. Anatomy, prize, W. Pinniger; certificates, F. W. Perry, A. Thomas, and J. S. Avery. University Entrance Scholarship (£50), C. S. Rivington. Lady Habersfield Entrance Scholarship (£30) A. E. Iles; Martyn Memorial Pathological Scholarships of £10 each, A. R. Short and C. Corfield; Tibbits Memorial Prize (£9 9s.), P. W. White; Committee's gold medal for the student of the fifth year who has most distinguished himself, J. E. Sparks; Augustin Prichard Prize (£6 6s.), C. J. Taylor; Clarke Scholarship (£15), A. Short; Henry Marshall Prize (£12), A. Short; Sanders Scholarships, J. E. Sparks (£22) and C. Corfield (£11); Special Midwifery Certificates, W. Blatchford, J. Clayton, F. Rudge, and C. J. Taylor.

**REQUESTS AND DONATIONS TO HOSPITALS.**—Mrs. Jane Lermite, of Thatched House, Muswell-hill, daughter of the late Dr. James Corrie of Finchley and widow of Mr. Edwin Walker Lermite, has bequeathed £300 to the North-West London Hospital to endow an Edwin Lermite cot.—By his will of Dec. 16th, 1895, with codicils of May 5th, 1896, and Dec. 22nd, 1897, Mr. Matthew Whiting of Auckland, No. 48, North-side, Wandsworth-common, whose

estate has been valued at £153,804 8s. gross, including personality of the net value of £140,870 18s. 7d., left the residue of his property (about £120,000) in trust in equal shares for St. Thomas's Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the Westminster Hospital, the Middlesex Hospital, the London Hospital, the Royal Free Hospital, St. Mary's Hospital, the Great Northern Hospital, the Brompton Hospital for Consumption and Diseases of the Chest, and the New Hospital for Women, Euston-road.—By the will of Alderman Sir Robert Sexton, of the firm of Robert Sexton and Sons, Dublin, dated April 17th, 1901, £500 are left to the Dublin Royal Hospital; £200 each to the Hospital for Incurables and the Royal Victoria Eye and Ear Hospital; £100 each to the Children's Hospital in Harcourt-street, the Orthopaedic Hospital in Brunswick-street, St. Patrick's Nurses' Home, and the Jervis-street Hospital.—St. Mary's Hospital has received a donation of 50 guineas from the Merchant Taylors' Company and a donation of £500 from Mrs. Vlasto, in memory of her husband, the late Mr. Alexander A. Vlasto.

**GUY'S HOSPITAL CHILDREN'S HOME.**—This institution has for its object the provision of a home in connexion with Guy's Hospital for the reception and maintenance of the infants of the women employed in the laundry, hostel, and elsewhere in the hospital, and of such other children as the authorities of the home may think fit to admit. The primary intention is to help young unmarried women with first babies, anxious to redeem themselves and ready to work steadily, that they may earn money for the support of their children. The home has been actively carrying on work since October, 1899. The mothers are required to contribute 5s. a week towards the board of their children, or this sum has to be guaranteed from an outside source, the balance required for the maintenance of the home being raised by annual subscriptions. In order that the full establishment of the home may be utilised, the treasurer appeals for additional subscriptions "in the strong belief that the appeal will be met by those who unite with the spirit of compassion an appreciation of its intelligent and practical exercise." Donations, gifts, or communications respecting the home should be addressed to Mrs. Wells, Friern Lodge, Westwood Park, Forest-hill, S.E. The report for the year 1900 states that 14 children had been admitted up to Sept. 30th, 1900, at which date eight were remaining in the home and three were awaiting admission.

**MEDICAL TOWN COUNCILLORS.**—At the recent municipal elections the following members of the medical profession were elected town councillors: Mr. Henry McQuade, M.D., B.Ch. Dub., at Bristol; Mr. Preston King, M.D., B.C. Cantab., at Bath; Mr. W. Paul Swain, F.R.C.S. Eng., at Plymouth; Mr. T. Stevenson Balfour, M.D., C.M. Edin., at Chard; Mr. Charles Edward Liesching, L.R.C.P. Lond., M.R.C.S. Eng., at Tiverton; and Mr. Maurice John Doidge, B.A. Cantab., M.D. Brux., M.R.C.S. Eng., at Glastonbury. In South Wales Mr. James Robinson, L.R.C.P., L.R.C.S. Irel., was returned at Cardiff, and Mr. Michael O'Sullivan, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., at Swansea.

**MUNIFICENT GIFT.**—The Executive Committee having charge of the arrangements for providing a consumption hospital for Worcestershire are carefully considering various sites and types of building which have been proposed and are inviting subscriptions. The following generous offer has been addressed to Mr. G. H. Fosbrooke, county medical officer, by Mr. Thomas Corbett:—

Impney, Droitwich, Oct. 25th, 1901.  
DEAR MR. FOSBROKE,—I have pleasure in informing you that I am now in a position to promise, on behalf of the estate of my late brother, Mr. John Corbett, a donation of £1000 to the building fund of the proposed county sanatorium for consumption for the county of Worcester. It is an institution my late brother was much interested in and which he was most anxious to promote, and if he had lived he would have been very glad to see successfully established. Feeling myself assured, as my brother did, of the good work which can be accomplished by means of such an institution, I take this opportunity of expressing my earnest hope that the scheme may be brought to a successful conclusion.—Believe me, yours faithfully,  
THOS. H. CORBETT.

**DR. HENRY DUTCH** has been returned by a majority of nearly 300 votes at the recent bye-election as councillor for the Grosvenor Ward of the city of Westminster, in the place of Colonel the Hon. Heneage Legge, M.P., resigned.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ANDERSON, EDMUND L., M.B., Ch.B. Vict., L.S.A. Lond., has been appointed Honorary Assistant Surgeon to the Hospital for Cancer and Skin Diseases, Liverpool.

BOND, FRANCIS THOMAS, M.D. Lond., M.R.C.S., F.R.S. Edin., has been re-appointed Medical Officer of Health by the Thornbury (Gloucestershire) District Council.

BREWERTON, ELMORE, F.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

BROWN, J. WALTER, M.B., B.Ch., R.U.I., has been appointed House Surgeon to the Royal Victoria Hospital, Bournemouth.

CUMMING, WILLIAM, M.D. Edin., has been appointed Health and Medical Officer at Cairns, Queensland.

EADES, A. J., L.R.C.P. & S.I., Assistant Medical Officer County Asylum, Prestwich, has been appointed Senior Assistant Medical Officer at the County Asylum, Winwick.

EVANS, C. W., M.B. Lond., has been re-appointed Medical Officer of Health for Bakewell.

FLETCHER, J. L., M.B., M.S. Edin., has been re-appointed Medical Officer of Health for the South Darley Urban District.

HADLEY, CLEMENT, M.R.C.S., L.K.Q.C.P.I., has been appointed Certifying Surgeon under the Factory Acts for the Shilton District of Warwickshire.

HALL, J. BASIL, M.C. Cantab., &c., has been appointed Honorary Surgeon to the Bradford Royal Infirmary, vice W. L. Roberts, M.R.C.S., deceased.

HARDING, H. W. L., M.R.C.S., has been appointed Public Vaccinator in New Zealand.

HOWARD, VINCENT, M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Borough and Rural District of Buckingham.

HOGG, JOHN A., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health to Castle Donington Rural District Council.

JACKSON, D., M.D. Glasg., has been appointed Medical Officer of Health for the Urban District of Hexham.

LANGHAM, W., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Axminster Rural District.

LLEWELLYN, J., M.R.C.S., L.S.A., has been appointed Medical Officer for the Sherburn District of the Scarborough Union.

MURRELL, CHRISTINE M., M.B., B.S. Lond., has been appointed Assistant House Physician to the Royal Free Hospital, Gray's Inn-road.

OGSTON, F., M.D. Aberd., has been appointed District Health Officer in New Zealand.

PARRY, T. W., M.B., B.S. Cantab., has been appointed Certifying Surgeon under the Factory Acts for the Youlgreave District of Derbyshire.

POLLEN, H., M.D. Dub., has been appointed Medical Practitioner under the "Workers' Compensation for Accidents' Act, No. 2" (Australia).

ROSS, MARION J., M.D. Glasg., has been appointed House Surgeon to the Morpeth Dispensary.

WARE, GEORGE STEPHEN, M.B., B.S. Durh., L.R.C.P., M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Fourth District of the Barnstaple Union, vice J. W. L. Ware, L.R.C.P., M.R.C.S., resigned.

WILSON, JAMES MITCHELL, M.D. Glasg., has been appointed County Medical Officer of Health for the East Riding of Yorkshire.

## Births, Marriages, and Deaths.

### BIRTHS.

ATKINSON.—On Oct. 26th, the wife of W. Alexander Atkinson, M.D. Durh., of a son.

BEKFRAGE.—On the 30th ult., at 2, Montagu-place, W., the wife of S. Henning Bekfrage, M.D., of a son.

BIDWELL.—On Oct. 30th, the wife of Leonard A. Bidwell, F.R.C.S., of a son.

TIPPETT.—On Oct. 22nd, the wife of Sydney Gordon Tippet, M.B. Lond., of a son.

### MARRIAGES.

BRYANT-WATTS.—On Oct. 31st, at St. Paul's Church, Cambridge, by the Rev. Dr. Stokes, LL.D., vicar, assisted by the Rev. L. B. Laurence, M.A., Charles Hilary, third son of E. Ross Bryant of Newcastle-on-Tyne, to Theodora Harvard Watts, fifth daughter of the late Thomas F. Watts and Mrs. Watts of Bracondale, Cambridge.

CARSBURG-FASTNEDGE.—On the 31st Oct., at St. George's Church, Stamford, Alfred Ernest Carsberg, M.A., M.B. Cantab., youngest son of George N. Carsberg, Esq., of Hornsey-lane, N., to Mabelle Ruth, youngest daughter of Richard B. Fastnedge, Esq.

GORDON-WILSON-RISCH.—On Nov. 2nd, at St. John's, Blackheath, by the Rev. Thomas Turner, vicar of S. Saviour's, Fitzroy-square, Alexander Gordon-Wilson, M.D. Lond., F.R.C.S. Eng., of Lyell House, Folkestone, to Louisa Mary Friederick Risch.

SAVILL-BLACKADDER.—At St. Mary Magdalene's Church, Dundee, on the 2nd inst., Thomas D. Savill, M.D. Lond., to Agnes F. Blackadder, M.A. St. And., M.D. Glasg., by the Rev. Francis Burdon, rector of St. Mary Magdalene's.

### DEATH.

SMITH.—On Oct. 29th, Henry Spencer Smith, F.R.C.S., in his 89th year.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### WARDS IN CHANCERY.

It occurs at times to medical practitioners desirous of supplementing their income by undertaking the charge of children and young persons in delicate health that the Court of Chancery, in the exercise of its jurisdiction over its wards, may be glad of their services, and that the court should have a fairly constant supply of young persons to be thus provided with desirable and suitable homes. A recent inquiry from a correspondent illustrates what we mean. He writes: "Could you give me the information of how and to whom to apply for the charge of a ward in Chancery? If you would do so I should be greatly obliged." Perhaps the best way to answer such an inquiry is to explain the position of the Chancery Division of the High Court of Justice in the matter of those young persons in whose welfare the Lord Chancellor is popularly supposed to interest himself personally. The Court of Chancery, as it is convenient to call it, will always undertake the superintendence and protection of the early years of those who possess money, if it is applied to with that object—for example, where money in which the infant is interested is paid into court under the Trustee Relief Act. A very small amount is sufficient to interest the court in the matter, and a parent desirous to obtain the aid of the court to prevent an imprudent marriage finds it convenient to do so by the settlement of a comparatively small sum of money, perhaps not more than £100, and complying with the necessary formalities, which sum the court will feel it its duty to shield from the possible future inroads of an undesirable bride or bridegroom. As a rule, however, wards of the court to whom such inquiries as the above might be held to refer are young persons entitled to property which may be large or small, but who have come to be wards of the court owing to some difficulty existing as to their rights, or some question having been raised as to the proper person to be appointed as their guardians. In any case someone has been interested in their career at some time and in consequence of that interest the court has been consulted, and if any question has arisen as to guardianship the court has settled it by appointing some person whom it has considered to be the proper person for the post. This person, whoever he or she may be, whether father or mother or a person in no way related, performs the duties of guardianship under the court's supervision; the ward is not to be taken out of the court's jurisdiction without its leave; an account is to be given of the methods adopted to secure his or her proper education, and the consent of the court must be procured to his or her marriage, or the wrath of the court will be incurred. The mere fact, however, of the possession of property, it will be seen, implies the existence of persons interested in the child's welfare and if there are infants in the court's charge as wards in Chancery in whom no one outside the court and its officials is interested they can hardly exist in sufficient numbers for any official, as our correspondent would seem to imply, having anything in the nature of a constantly recurring function to exercise in the choice of homes for children in weak health. The care of those whose deficiency is mental depends upon the establishment of the mental unsoundness which afflicts them, but the jurisdiction exercised by the Lord Chancellor and the Lords Justices of Appeal in matters which concern lunatics has nothing to do with that which is exercised by the Court of Chancery over infants whose property has been entrusted to the care of the court. In conclusion, we may say that the ward in Chancery is an infant whose guardian is subjected to supervision by the court owing to his possessing property in which the court is interested, but that we are not aware of any officially recognised method by which the temporary care of the infant's body may be obtained.

### MARSHALL HALL'S METHOD OF RESUSCITATION.

To the Editors of THE LANCET.

Sirs,—In reply to your correspondent "P. T." in THE LANCET of Nov. 2nd, p. 1240, he can find the account of Dr. Marshall Hall's method for the resuscitation of the apparently drowned in "Osborn's First Ambulance Lectures," published by Lewis, Gower-street. It is as follows. The patient is laid upon his face with one arm flexed and placed as a cushion for his forehead to rest upon and his chest supported by folded articles of clothing. The opposite arm is then taken by the wrist by one hand while the other hand rests on the patient's shoulder-blade of the same side, the body is then turned on its side and a little beyond and the arm which is being held by the wrist is elevated above the head; by this means inspiration is effected. The body is then turned back on to the face whilst pressure is made with the hand resting on the thorax sufficiently to drive the air out again and expiration is simulated. Two assistants, one taking the head and the other the lower extremities, follow the operator in his movements when turning the body backwards and forwards.

I am, Sirs, yours faithfully,

Nov. 4th, 1901.

H. T.

### THE OBLIGING OPTICIAN.

A CORRESPONDENT has sent us a cutting from the *North Devon Herald* of Oct. 24th, by which we are informed that Mr. A. E. Dark, F.S.M.C., B.O.A., Spectacle Specialist (Diploma by examination from the Worshipful Company of Spectacle Makers, London, 1899), lives at 14, High-street, Barnstaple. Mr. Dark says that all errors of refraction are correctly diagnosed and that difficult cases and those considered impossible to suit with glasses are specially sought for. He keeps a special eye-testing room and neither time or (*etc*) trouble is spared in testing, with the result that glasses prescribed by him are in almost every case faultless for clearness and comfort. We have not the least idea what F.S.M.C. may mean or B.O.A. either, for the only body with which we have any acquaintance is an animal whose chief characteristics are entrapping unwary prey and then swallowing it. Mr. Dark had better confine himself to his proper trade of grinding lenses to a curvature the figures for which may be supplied to him by a properly qualified medical man.

### GRATITUDE.

A CORRESPONDENT has sent us the following letter:—

To Dr. A—,

Sir,—I, J. R., do wish hereby to express to you and your Assistant, Dr. D., my deep felt gratitude for, and appreciation of, the kindness, patience, and skill displayed by you in the treatment of my wife in the crisis through which she passed in the early months of this year which will ever be remembered by us. Likewise the sympathy and treatment in our other trials is remembered by us with respect and deepest gratitude. Wishing you may always have like success in your undertakings,

I remain, your humble servant,

J. R.

Dr. A— is rightly gratified at such a testimonial. These are the little things that sweeten the medical life, while they remind the medical man that his calling is not a pure trade, inasmuch as the intimate service which he may be called upon to render to his patients can never be paid completely in money.

### AN ENVIABLE OPPORTUNITY

To the Editors of THE LANCET.

SIRS,—I note that you allude in a leading article in THE LANCET of Nov. 2nd, p. 1207, to the enviable opportunities that dentists seem able to enjoy for fishing—among other pursuits. I was speaking a day or two ago to a friend of mine, a dentist and a fisherman, upon the subject, when he handed me the inclosed record of his catches from Oct. 1st to 26th inclusive. He seemed to consider that the reproach of wasting his time could not well be brought against him,

I am, Sirs, yours faithfully,

Nov. 5th, 1901.

### ADVERTISEMENT IN EXCELSIS.

In the issue of M.A.P. of Nov. 2nd Mr. T. P. O'Connor mentions that he prescribed "the dry meal" as a specific for dyspepsia. Without stopping to do more than say that it is foolish for a layman or even for a medical man to "prescribe" any one remedy for a condition which depends upon so many things as that of dyspepsia, we presume that Mr. O'Connor means that eating without drinking relieves some forms of dyspepsia. However, Mr. O'Connor has been called indignantly to task by "Dr. Yorke Davies, the eminent specialist on food and digestion." Now, Mr. Yorke-Davies, who has the qualifications of M.R.C.S., L.R.C.P. Lond., L.S.A., and L.M. Dub., writes to Mr. T. P. O'Connor and points out quite rightly the danger of prescribing in the lay press. So far so good; but when he proceeds, as he does, to say in so many words how skilled he himself is in the treatment of dyspepsia we must protest. Take the following sentences: "I diet thousands of people." "I suppose there is not a day that I do not get patients ..... "I have dieted many thousands for this purpose, and in no single case has one ever come to me for this, where they have not been able to say that they benefited by the process." Mr. Yorke-Davies also remarks: "I think I know a little about literature and writing, as I have been a writing-man all my life." We are glad to know this at

first hand for from the following sentence we should never have thought it. "If a person wants to lose weight advise them to go to the expert who can do it without harm." Lest there should be any doubt as to who the expert is Mr. Yorke-Davies kindly adds: "Many patients of Schweninger, whose system of reducing weight is the dry one, come to me." Why patients should be benefited by seeing Mr. Yorke-Davies lose weight we cannot understand. After the thousands of patients who have seen him he must be in the condition of Augustus, of whom it may be remembered the poet (a medical man) remarked—

"Look at him now the fourth day's come,  
He scarcely weighs a sugar-plum."

We may add that we have received two letters of protest against this unblushing advertisement, one from a medical man and one from a layman.

#### ISAAC GORDONS AND THE MONEY-LENDING ACT (1900).

WE have received a little pamphlet from Mr. Thomas Farrow, whose book, "The Money Lender Unmasked," led to the passing of the Money Lenders Act, 1900. True, Mr. Farrow contends that the Act is perfectly useless, and he gives quotations from the *Law Times* and from *Truth* to support his contention. Mr. Farrow mentions a number of reforms which he considers should be useful, and, to our minds, the Act certainly ought to be amended upon Mr. Farrow's lines. Young medical men frequently fall victims to these sharks' delusive advertisements, so that we, as medical journalists, have a personal, if possibly selfish, interest in seeing money-lenders checked.

#### THE METHODS OF A PUBLIC VACCINATOR.

ON two previous occasions we commented (see THE LANCET, August 17th, p. 502, and Sept. 14th, p. 768) upon the methods of a certain public vaccinator. In both instances we withheld the gentleman's name. As, however, the circular continued to be sent out we wrote to him calling his attention to what we had said. We received a reply which we do not think is satisfactory. However, he mentions that he courts publicity; therefore we publish his name and address—Dr. Theo. Parker, Beryl, South Norwood.

#### A CASE OF MALINGERING.

To the Editors of THE LANCET.

SIRS,—A man, giving the name of Charles Turner, aged 49 years, came in here one wet morning saying that whilst at work on the Great Northern Railway at Royston repairing telephone wires a telegraph pole had fallen across the front of his abdomen, knocking him down and rendering him unconscious for two hours. The accident occurred at 8 A.M. He said he vomited on recovering consciousness and again on reaching the infirmary at 11 A.M. On examining him the abdomen was tense and rigid; there was no tympanites. He complained of severe pain and tenderness. Urine was passed two hours previously; some was drawn off with a catheter and was normal in every respect. An old laparotomy scar was observed on the abdomen. The skin was cold and moist and his temperature was 97° F. I was told by the matron that she remembered having seen a similar case at Norwood Cottage Hospital some years ago which proved to be a fraud and had the patient carefully watched. The surgeon under whose care he was came to the conclusion after four days' observation that there was nothing the matter with the man and he was eventually turned out of the infirmary. He has a trick of adulterating the urine with tobacco-juice, and by slow degrees makes himself obnoxious to the nurses. The man has, I believe, been at Royston Cottage Hospital, from which he departed at 5 A.M. one morning. He then came on here. He sometimes gives the alias of Charles Stevens, but his tale is usually the same. He gives a false address in London, travels by himself, and he said he worked for the National Telephone Company, which is untrue. I inclose a photograph of the abdomen; he objected to have his face taken.

I am, Sirs, yours faithfully,

H. DONALDSON-SIM.

General Infirmary, Hertford, Oct. 29th, 1901.

\*.\* The photograph which our correspondent incloses shows an apparently very tense distended abdomen, the distension being specially marked along the line of the transverse colon. Mr. Donaldson-Sim, however, expressly says that there was no tympanites. Probably if the nature of the case had not been detected the man would have gone on to produce a phantom tumour.—ED. L.

#### "TEGMINE."

"TEGMINE" is the name given to a sticky and aseptic preparation of oxide of zinc which is intended to be spread over the spot where the scarifications in vaccination have been made. Before the smear of tegmine has hardened a circular textile pad may be placed over it. Tegmine dries very rapidly and its application with the pad obviates the use of other protective appliances. The method is cleanly and neat, with no unsightliness at all. Scars look very healthy usually under this simple but effective dressing. Tegmine is sterilised by steam and drawn into sterilised zinc tubes by air-pressure. The small outfit submitted to our notice was sent to us by Messrs. Rebman, Limited, 129, Shaftesbury-avenue, London, W.C. It is stated that tegmine has been described at the Imperial Institute for the Cultivation of Calf Vaccine in Vienna as "the most suitable and reliable protection in vaccination."

M.D. (Bournemouth).—There is no tariff that will exactly meet such inquiries. The practitioner will best judge for himself, having generally special knowledge of the means and circumstances of his patient and of the value of his own time. Three guineas and five guineas would appear reasonable fees for the services rendered in the respective cases. But our correspondent must use his own judgment.

Country Practitioner.—We are not quite certain of the price and date of the later editions of the best books but will reply in the course of the week.

Streatham.—The law is perfectly clear on the matter and a solicitor's advice is all that our correspondent requires.

ERRATUM.—We regret that through an error the name of Messrs Martell and Co., the well-known producers of brandy in the Cognac district, was given in our analytical notice of Pedigree Port last week. Messrs. Martell and Co. are in no way connected with the Pedigree Port Company, the proper address of which is Gt. St. Helen's, London, E.C.

ERRATUM.—In THE LANCET of Oct. 26th, p. 1153, col. 1, line 17, "Major E. J. Lloyd to be Surgeon-Lieutenant" should read Surgeon-Lieutenant-Colonel.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

### OPERATIONS. METROPOLITAN HOSPITALS.

**MONDAY (11th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (12th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY (13th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY (14th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY (15th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**SATURDAY (16th).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

### SOCIETIES

**MONDAY (11th).**—MEDICAL SOCIETY OF LONDON (11, Chandos street, Cavendish-square, W.).—8.30 P.M. Clinical Evening. Mr. A. Pearce Gould: Two Cases of Actinomycosis.—Mr. Monier-Williams: Case of Ulcerative Colitis treated by Colotomy. Paralysis of Eleventh and Twelfth Cranial Nerves.—Mr. T. H. Kellock: Case of Bilateral Disease of the Ankle-joints in a Child.—Mr. C. Mansell-Moullin: Case of Spina Bifida Occulta.—Mr. A. Carless: Case of Amputation of Entire Upper Extremity for Chondro-sarcoma, with specimen.—Mr. J. L. Thomas, C.B.: (1) Photograph of a Large Occipital Meningocele cured by Operation; (2) A New Reel for Multiple Ligatures.

**TUESDAY (12th).**—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper.—Mr. C. B. Keestley: Ulceration of the Oesophagus and Stomach due to Swallowing Strong Hydrochloric Acid, Lessons of Treatment deduced from Three Cases.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury square, W.C.).—8 P.M. Papers:—Mr. T. E. Wallis: The Structure of Capsicum Minimum.—Mr. W. H. Lenton: The Ash of Capsicum Fruits.

**WEDNESDAY (13th).**—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Demonstration of Cases of Interest.

HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Discussion on Small-pox and Vaccination in which Dr. W. A. Bond will take part. Paper: Dr. Major Greenwood: The Present Position of Small-pox and Vaccination. Dr. MacCombie: The Differential Diagnosis of Small-pox, with remarks on Prodromal Rashes and Vaccination.

**THURSDAY (14th).**—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Mr. B. Browne: Twenty-five Years' Experience of Urinary Surgery (Harveian Lecture.)

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Dr. H. Macnaughton-Jones, Mr. R. O'Callaghan, and others. Paper: Dr. H. Snow: Prophylaxis in Gynæcology.

**FRIDAY (15th).**—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos-street, Cavendish-square, W.).—5.30 P.M. Cases and Specimens will be shown by Mr. A. H. Tubby, Dr. D. Walsh, Mr. S. Stephenson, Dr. E. Cautley, and Mr. W. G. Nash. Papers: Dr. E. Cautley: Observations on the Etiology and Morbid Anatomy of Tuberculous Meningitis.—Mr. G. Pernet: A Family Epidemic of Impetigo Contagiosa Bullosa.

#### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (11th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. J. F. Payne: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. H. Li. Williams: Diagnosis of Pain in the Teeth.

**TUESDAY (12th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Sir W. H. Broadbent: Clinique. (Medical.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Ormerod: Cases in Hospital.

ROYAL UNITED SERVICE INSTITUTION (Whitehall).—3 P.M. Dr. L. Canney: Typhoid, the Destroyer of Armies, and its Abolition (followed by a Discussion).

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Medical Anatomy.

**WEDNESDAY (13th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. E. W. Roughton: Clinique. (Surgical.)

LONDON THROAT HOSPITAL (204, Great Portland-street, W.).—5 P.M. Dr. F. Potter: Selected Cases. (Post-Graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Maguire: Aortic Regurgitation (with cases).

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—8 P.M. Dr. W. Wingrave: The Examination of the Ear.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Minor Surgery.

**THURSDAY (14th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Kellock: Abscess in connexion with Spinal Caries and its Treatment.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Gibbs: Demonstration of Surgical Cases. (Post-Graduate Course.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Keetley: Unreduced Dislocations.

**FRIDAY (15th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. H. Tilley: Clinique (Throat).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Risien Russell: Paraplegia.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Dunn: Ocular Symptoms.

#### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, and WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

#### MANAGER'S NOTICES.

##### TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 12 6	One Year	...	£1 14 8
Six Months	...	0 18 3	Six Months	...	0 17 4
Three Months	...	0 8 2	Three Months	...	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET OFFICES, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

#### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Subscriptions (which may commence at any time) are payable in advance.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Amiens, Paris.

*The Harveian Lectures*  
ON  
**TWENTY-FIVE YEARS' EXPERIENCE OF  
URINARY SURGERY IN ENGLAND.**

*Delivered before the Harveian Society of London*

By G. BUCKSTON BROWNE.

LECTURE I.<sup>1</sup>

*Delivered on Nov. 7th, 1901.*

MR. PRESIDENT AND GENTLEMEN,—In thanking the Harveian Society for the honour which it has conferred upon me in inviting me to deliver the Harveian Lectures I should like to remark upon the unusual nature of the society's choice. The Harveian Society has invited a purely private practitioner to lecture before it. My life since I left University College Hospital and School in December, 1874, where I was first of all house surgeon and then demonstrator of anatomy, has been entirely devoted to private practice. At the end of the year 1874 I was invited by Sir Henry Thompson to join him as his assistant and for the next 14 years we were side by side. He never operated without my being present and I practically saw all his patients with him. These 14 years were very active and full of experience and opportunity. When they came to an end I worked on alone, not less actively, so that I have had 27 years in one great department of surgery—namely, the surgical diseases of the urinary organs, and I propose to devote this present course of lectures to what I think I have learned in these years and to attempt to give my reasons for the faith which I believe in me. Just as in ovariectomy and in all abdominal surgery peritonitis was in the early days the great dread of the surgeon, so in urinary surgery fever was the great fear of the operator. And this fear controlled, influenced, and in fact dominated all his movements and all his plans and checked all his enterprise. If he passed a lithotrite or employed a catheter he often found that fever followed, and a fever which not infrequently proved fatal. The surgeon therefore interfered as little as possible with the urinary passages and for many years but little real progress was made.

I propose at once to consider the question of urinary fever, for it is at the bottom of the whole of urinary surgery. Wherever you touch urinary surgery you find this fever, and even now its causation and therefore its prevention is very little understood. In all our books you find vague and uncertain statements. I believe this fever to be at its outset purely a suppression of urine, varying from merely transitory to the most complete and absolute, this suppression being due to the inhibition of the action of the kidney from urethral shock. The nerve-supply of the urethra is remarkably generous and the penis itself is most intimately connected in this way with the rest of the body. An excellent illustration of the very liberal nerve-supply of the urethra and of its intimate connexion with the rest of the body is afforded by the study of the marvellous phenomena of erection. In the pre-chloroform days many a man has died upon the operating-table simply from the shock of an amputation of the penis. If a bougie is passed upon the average young man in the standing posture he will in many cases in a few moments be writhing on the floor in what is practically an epileptiform convulsion; let him be put to bed, and a good perspiration encouraged, and he will soon be well; but if an old man be subjected to a similar shock he does not always recover. Many surgeons of sufficient experience will be able to recall some case of an elderly man who has had a catheter passed and who has never secreted another drop of urine and has died. In illustration of the effects of shock and of its control by the use of sedatives I well remember a nervous, sensitive, highly-strung young practitioner who came to me with a severe urethral stricture. The gentlest instrumentation was followed by high fever. I fortunately thought of giving him one-sixth of a grain of morphia hypodermically

an hour before passing the bougie. This was followed by the happiest results: there was no fever and dilatation was easily proceeded with. Some years ago I had even a more instructive case than this with my old fellow-student Dr. Peter Duncan of Croydon. He called me to a case of an elderly gentleman with retention of urine and a long history of urethral stricture. The case was urgent and with great care and not easily I passed a No. 1 silver catheter and drew off a large quantity of urine. Next day I found the patient comatose and so ill from urinary fever that both Dr. Duncan and I thought he would die. He responded, however, to active treatment and made a good recovery. The question then was, what was to be done to the stricture? It must be treated, but if the simple passage of a No. 1 silver catheter was nearly followed by death, what would happen if the interference was more radical than that? Sir William Broadbent supported me in my proposal to perform my operation of internal urethrotomy at one sitting under an anæsthetic. A clean cut through the fibres of the stricture was followed by the best results. There was no fever, no illness of any kind, and the patient lived for several years in perfect urethral comfort. We often find in practice that the stricture patient can bear a certain sized bougie well, but if an instrument at all larger is used its introduction is sure to be followed by fever. I have often found that a medical friend is very much surprised when it is pointed out to him that however often he has had to deal with urinary fever in male adults he has never had to do with it in women or in children of either sex, for women and children never suffer from this fever. Now do not all these facts prove that the fever is due to nervous shock, to urethral shock? The male adult's urethra is a sexual as well as a urinary tract, his penis is highly endowed with nerves, and it is precisely he who suffers from this fever. The urethra of the woman and child is a urinary tract only and they do not suffer. Deal gently with the male urethra and all will probably be well; use violence and the results may be disastrous. Narcotise the patient with opium or with chloroform and you may use violence up to a certain point and still have no fever. You may often cut the urethra, if you do not stretch it, and have no fever. You may one day pass a catheter and have no fever, and next time and on the same patient you may not be so skilful and successful, you may blunder and hurt the patient and make him bleed, and severe fever will follow. Then, again, it is impossible to practise for many years among patients troubled with urinary disorders without observing that certain nationalities are more prone to this fever than others. The French are certainly much more susceptible than the Germans, and among the British the Irishman is far more likely to suffer than the Englishman. These more susceptible people are certainly the most nervous, this term being used in its highest and best sense, for many will agree that the Irish and the French are the two cleverest peoples in the world. Even amongst people of the same nation, the more highly trained, the more educated, the more refined the subject, the more likely is he upon due provocation to suffer from this fever. The physician, the poet, and the painter are certainly worse subjects for operation where the urethra is concerned than the labourer and the uneducated classes generally. All these clinical facts prove that the onset of urinary fever is due to nervous urethral shock conveyed to the secreting tissues of the kidneys by the urethral nerves and inhibiting the secretory action of these organs to a lesser or greater extent, producing suppression of urine, from the most complete and absolute to the slightest and most transient possible. In fact, urinary fever is suppression of urine. If the suppression of urine is complete or considerable the kidney naturally becomes engorged with blood, inflammation ensues, and in bad cases suppuration follows, and the patient frequently sinks into a state, often and deservedly called typhoidal, and dies. No doubt this suppuration is more likely to occur if there be surgical impurity in the bladder, and hence the necessity for careful antisepticism from the very commencement of any surgical urinary treatment. My view, therefore, is that while this urinary fever may undoubtedly run on and develop into septicæmia, it is not, primarily, blood-poisoning. A clear view of this subject will be an excellent guide in practice, helping us to prevent as well as to cure, it will save us from all the dangerous fallacies which result from huge and undigested statistics, from drawing conclusions from operations on one race of people and applying them to all other races, and it will make the history of urinary surgery clear, reasonable, and instructive, whereas without this definite

<sup>1</sup> Lecture II. was delivered on Nov. 14th and Lecture III. will be delivered on Nov. 21st.  
No. 4081.

understanding much may appear irregular, uncertain, and extraordinary.

In 1875, when I began practice, a man with a stone in his bladder was subjected to either perineal lithotomy or to lithotripsy, and occasionally large quantities of small stones were simply washed out of the bladder by Clover's apparatus, a good instance of this latter operation being published by the late Mr. John Foster in THE LANCET of Oct. 10th, 1874, four years before Professor Bigelow published his paper on Litholapaxy. The woman with a stone was generally cut and boys and girls were always cut. Lithotripsy was unquestionably an unpopular operation. The general surgeon was opposed to it, although Liston, Brodie, and Fergusson had all given it their countenance. Sir Henry Thompson, in his time, was almost alone in this country, as an advocate and champion of the operation, urging its adoption not as a substitute but as a complement to the operation of lithotomy. Sir Henry Thompson is without doubt the most prominent figure in urinary surgery during the latter half of the nineteenth century, and it will be my earnest endeavour to make clear the part which he has played and the principles which he has consistently adhered to throughout his career. He is happily still amongst us, but I speak entirely on my own responsibility. I speak strongly on this matter, for he has been, over and over again, unworthily attacked by those who, finding that he did not know and foresee everything, have failed to give him credit for the great work which he has done and have not been sufficiently generous to admit how much they owe to him. The early lithotritists of course had to practise without anaesthesia, and they found that patients bore badly the repeated introduction of instruments, and that the more instrumentation they underwent the more severe was the resulting urinary fever. This led Civiale, the father of lithotripsy, to inculcate the importance of short sittings and of the employment of great gentleness, and it was with this teaching that Thompson was imbued when he began his surgical career in London. Sir Henry Thompson became emphatically the propagandist of gentleness in urinary surgery in this country. This principle of gentleness is a great one, and is still of vast importance, although the introduction of anaesthetics has made it subject to certain modifications. The lithotrites of 1860 were the ingenious and unhandy instruments of Brodie and Fergusson and the perfect instrument of modern days is entirely due to the suggestion of Thompson and to the mechanical genius of the elder Weiss. No one but the lithotritist can realise the value of the cylindrical handle which they introduced. For some years Sir Henry Thompson practised lithotripsy, removing much of the debris between the blades of the lithotrite and leaving the rest to be expelled by nature's efforts, and it was not until 1866 that the late Mr. Clover's name began to be associated with the operation of lithotripsy. In THE LANCET of May 11th of that year he first described his apparatus for evacuating the debris after the crushing of a stone. No one has ever done sufficient honour to the memory of Mr. Clover. He was an Englishman educated at University College Hospital, London, full of ingenuity and resource. His inventions were numerous and he was a pioneer in the modern art of anaesthesia, and in that art his inventions are still in use and are of great value. In turning his attention to anaesthetics it seems to me uncertain whether that art gained or general surgery lost the more. At any rate, his apparatus for evacuating stone after lithotripsy is unquestionably the prototype of all modern evacuators, and in it lay the germ of the whole of modern lithotripsy. It is curious in reading the early literature of this subject to note how right Clover was in everything he taught and pointed out from the very beginning. Twelve years afterwards, when Professor Bigelow of Boston introduced his evacuating apparatus, it consisted of Clover's syringe with the receptacle of glass below and the top connected with the evacuating catheter by a long flexible tube. Clover had taught and explained that the nearer the glass receptacle was to the penis the better, and after more experience Professor Bigelow accepted Clover's teaching and did away with all connecting tubing. Clover taught that the smaller the evacuating tubes, the less water would they contain, and therefore the brisker the current within them. Bigelow's immense tubes have been found unnecessary and Clover's smaller ones have been employed. Clover's tubes were short, Bigelow's were long, and now all our tubes are as short as possible. Every one of Clover's tubes was fitted with that most important adjunct, a flexible stylet. Bigelow's tubes had no such stylet, though he spoke of clearing his

straight tubes with a rod, and now no lithotritist would use a tube without its being fitted with a flexible stylet, again showing how right Clover was. Clover's tubes had lateral plates or rings at the distal end. Bigelow's had not these lateral plates which permit of the easy rotation of the tube when in the bladder and of the compression of the penis, rendering the route to the bladder all the shorter; now every operator uses these plates or rings. I think all this makes it quite clear that even Bigelow himself, and certainly all his followers, had to go back to Clover's principles, and for these principles, I assert, sufficient acknowledgment has never been made to our distinguished countryman. I believe Clover never operated for stone in his life; if he had been an operator it is more than likely that using his evacuator, and with the assistance of anaesthetics, he would have anticipated Professor Bigelow by 12 years; instead of that he handed his apparatus to Sir Henry Thompson and contented himself with the administration of anaesthetics. The largest of Clover's evacuating tubes is No. 16, English, and I have the pleasure of showing it to-night, for he left a written request that I should have all his surgical instruments. This size is the one I still use. I rarely employ No. 17 or No. 18 and never any larger size. It is quite untrue to say that with Clover's apparatus only a little sand was washed out. With his No. 16 tube large fragments were removed and the apparatus was a very useful one. At this time (1866) Sir Henry Thompson was beginning to employ anaesthetics during his sittings of lithotripsy, but only in private practice. In the hospital he still operated without chloroform, and in employing Clover's bottle there he found that while the patient bore the introduction of the lithotrite in the crushing of the stone with fortitude he would often complain, and that bitterly, when the bladder was distended in the operation of evacuation. This led him, thoroughly inspired with the importance of gentleness and of reducing the urethral shock to a minimum, to employ the evacuator without great enthusiasm. Still the instrument gradually forced itself into his esteem, and when I joined him we took it to every operation and invariably employed it. Our practice then was nearly all in private and the patients, therefore, were always anaesthetised. Here is a letter from Mr. Clover to me dated Jan. 29th, 1882:—

MY DEAR BROWNE.—On referring to my notes I find that I gave the anaesthetic 130 times whilst Sir Henry Thompson performed lithotripsy in the years 1876 and 1877, and in nearly all these cases he made use of the aspirator to remove fragments. The exceptions would not amount to 10 per cent.

Yours truly,

J. T. CLOVER.

During this period both Sir Henry Thompson and I would often crush a stone and wash it out entirely at one sitting. Mr. Clover, in a letter to the *British Medical Journal* of Nov. 16th, 1878, refers to my doing this, but we thought nothing of it, and it was only if a patient suffered severely from cystitis after a sitting of lithotripsy that Sir Henry Thompson would, as it were, harden his heart, send for Mr. Clover to anaesthetise, and then and there clear out all the remaining debris, thinking it better practice to subject the urethra and bladder to considerable disturbance rather than allow the irritating fragments of stone to remain. But this was the exception and not the rule, and here we see distinctly that Sir Henry Thompson had the defects of his virtues, for if he had been less gentle he would have been more bold. And so we went on for three years, when in the autumn of 1878 Professor Bigelow proposed to treat calculi within the limits of lithotripsy by crushing and evacuating at one sitting. The principle was soon recognised to be of the very first importance, and taking the profession all over the world as a whole it was accepted with remarkable openness and fairness of mind. There is no doubt that Sir Henry Thompson was surprised when he found how near he had been to the discovery of this great principle; we cannot say, without seeing it at all, for he had seen it, veiled, in a mist, but without realising its greatness and universal applicability. He would doubtless have accepted it at once had not the great principle unfortunately been overloaded by Professor Bigelow with the use of huge lithotrites and of large evacuating tubes. These large instruments offended Sir Henry Thompson's feeling of surgical respect for the male urethra and excited his dread of urinary fever. In my opinion Professor Bigelow was not altogether right or Sir Henry Thompson altogether wrong. As regards myself, I have done my work since 1878 acting upon Professor Bigelow's principle, but with my lithotrites and my evacuating tubes practically

unchanged, but employing Professor Bigelow's improvement of Clover's bottle, the improvement in that instrument consisting in putting the rubber syringe above the glass receiver instead of horizontally beyond it, while at the same time I have taken away Professor Bigelow's internal tube, reducing the interior of the tube to its original simplicity. Throughout I have been faithful to Sir Henry Thompson's teaching and have never failed in my respect for the male urethra, always using the smallest instrument practicable and in the gentlest manner. Bigelow's suggestion was, after all, only an extension of Thompson's teaching. Thompson was kind, Bigelow apparently more cruel was kinder still, to the parts concerned. Professor Bigelow, in addition to the use of large instruments, proposed to call his alteration in the method of lithotripsy by another name altogether—namely, litholapaxy (*λῆθoς* stone, *λαπάξω* to carry off). This, I think, was altogether a mistake and unfair to lithotripsy which was not superseded or rendered obsolete, but simply had its field of usefulness extended. The term "locomotive steam-engine" describes the crude "Puffing Billy" of George Stevenson, but it is quite as applicable to the most modern flyer just turned out of Crewe. Just so an extension of the operation of lithotripsy which is still essentially a crushing operation needs no other name. I think, however, as I shall explain further on, that we want another name such as litholapaxy, but not in the sense employed by Bigelow.

It has often been asked, "What is a stone in the bladder?" My definition is that a stone in the bladder is concrete calculous matter which the patient is unable to get rid of naturally. A stone in the bladder may therefore weigh anything from two to three grains to several pounds. Even if a stone has left the bladder and being arrested in the urethra is pushed back into the bladder prior to its removal, it should still, I think, be considered a stone in the bladder. In fact, directly a renal stone is extruded from the ureter it becomes a stone in the bladder. When once the presence of a stone in the bladder has been detected the best plan to remove it has to be considered. It has not been generally recognised that there are really three ways of removing a stone from the bladder. It may be removed by vesical incision, lithotomy; it may be crushed and washed out, lithotripsy; and it may be washed out whole through a tube; and it is to this latter proceeding that I would confine the term "litholapaxy." If these three operations are not admitted to be distinct, where, then, are you to put the calculi pumped out through tubes? They certainly cannot be entered under "lithotripsy" and they certainly cannot be admitted under the heading of "litholapaxy," if there you record your lithotrities, without obvious unfairness and confusion. When Professor Bigelow established the fact that it was safer to crush a stone and suck out every particle in one operation than by several he wished to distinguish his single-sitting operation from the older and many-sitting one, and being by no means certain (only having an experience by himself and others of 14 cases) that it would entirely sweep away the old method named his operation litholapaxy, which merely means the evacuation or removal of stone. This new term might have been justified if lithotomy had been swept away as well as the old lithotripsy, but as this is not the case I propose that the terms "lithotomy" and "lithotripsy" shall stand, "lithotripsy" meaning Bigelow's lithotripsy, and that we confine the term "litholapaxy" simply to those cases where a stone or stones can be pumped out entire through tubes.

Litholapaxy, in my sense of the term, is the simplest and safest of the three methods, and if the stone or stones be small the operator should always attempt removal by means of tube and aspirator, and should only crush if the stone be too large to come through a No. 16, No. 17, or No. 18 (English scale) tube. Lithotripsy, that is to say, Bigelow's lithotripsy, lithotripsy at a single sitting, is the operation for boys and girls, women and men, in all uncomplicated cases of stone in the bladder. Operators vary in skill and experience, and one man may be able to deal successfully with a large or a hard stone which would baffle a less experienced surgeon. Much must depend upon the individual, and the surgeon will be well advised if he subject his patient to lithotomy in all cases where he feels uncertain that he will be able to break and bring away every particle of stone at one single operation, for that is the essence of modern lithotripsy.

It is when faced with large stones in elderly and feeble men, and particularly when there has been long-standing prostatic or other obstructive disease, that I think the modern

lithotritist should pause. Supposing that the stone is not mechanically beyond the limits of the lithotrite it must be remembered that the old man's urethra ill bears the repeated introduction of large lithotrites and tubes. The prostate may be so disturbed that no urine is passed afterwards except by catheter, and the mucous membrane of the bladder may be so injured that phosphatic deposits readily occur and plague and torture the remaining years of life. In many of these cases the interests of the patient will often be best consulted by the removal of the stone through a suprapubic vesical incision. Then there are many cases where it is impossible to clear thoroughly an old bladder from stone by instruments introduced through the natural passages. There is the post-prostatic or trigonal pouch illustrated by me in THE LANCET of April 18th (p. 867) and 25th (p. 922), 1891; there is the lateral prostatic pouch described and illustrated by me in the *British Medical Journal* of Oct. 12th, 1895; there is the post-trigonal pouch; and there are the regular sacculi, which consist of the protrusion of mucous membrane between the muscular fibres of the bladder. In all these pockets stones or fragments of stone may lodge and may defy the most careful attempts of the best lithotritist, not only to remove them, but even to detect them. The entrance to many of these pouches is very small and can only be got at by a suprapubic incision. Then the bladder itself in many of these cases is actually coated with phosphatic matter which cannot be got away with the lithotrite. I would say, therefore, that if on examining an elderly man his urine is found to be clear and free from pus and the stone is felt to be of uric acid or of oxalate, and not large, say, not over three ounces, it will probably be safe to perform lithotripsy. But if the urine is purulent and alkaline, the prostate very large, and the stone large and phosphatic, I think in most cases the best result will be attained by a suprapubic lithotomy.

One of the old axioms in the art of lithotomy was that you should never cut for the stone without having felt the stone with staff or sound immediately before making the incision. The following experience shows that even this valuable old rule has its exceptions and proves what I have just stated, that we cannot dispense with lithotomy. I was called by Mr. Noble Bruce to see an aged gentleman. Feeling sure from his symptoms that he had a stone in his bladder I sounded him and at once came in contact with a stone which appeared to be one of fair size. I made all arrangements to perform lithotripsy, and on the appointed day the patient was anaesthetised and I commenced proceedings, but do what I would I could find no stone. I tried every position of the patient and made rectal pressure in vain. The situation was one of great embarrassment and the anxious friends were eager for the news that all was safely over. After a most patient but fruitless search I was obliged frankly to tell them that I was satisfied that I had not been deceived, that there was a stone there, but that owing to a pouch or pocket of some kind I could not on this occasion even touch the calculus, much less seize and crush it. The patient took a day or two to consider matters and then consented to my performing suprapubic lithotomy. I found an extraordinarily deep post-prostatic pouch and at its bottom a stone measuring five inches in its largest circumference. The patient made a good recovery. It is the difficult cases that must be cut, and it is precisely the difficult cases where suprapubic lithotomy is the operation. I look upon perineal lithotomy as obsolete. No finger is long enough to explore thoroughly the bladder through a perineal incision and even if it be admitted that it is long enough to make a complete diagnosis, it is certainly not long enough to do any work in the bladder, to turn a stone out of a pouch, or to stretch and dilate the neck of such a pouch before getting out the stone. I have had several cases where nothing could have been done from the perineum, but the finger introduced suprapubically was able to get directly to the stone to stretch the neck of the sac, and finally with scoop or forceps to aid in the extraction of the stone. On one patient I was once obliged, in the course of five years, to perform three suprapubic lithotomies. He was an old stricture patient, and 10 years before I saw him had had a perineal section performed. From long-standing urethral obstruction the bladder had become badly pouched. In the trigone of the bladder there was a large pocket, which caught and retained the rather large calculi which constantly came down from the kidney. It was impossible to get these stones away except by suprapubic incision, they could be detected by the vesical sound, but could not

be seized by the lithotrite. With reference to the return of stone after operation I do not think statistics are important. It must be remembered that after either crushing or cutting the same constitutional conditions remain, and that the constitution may just as easily after one operation as the other form another stone. The same local conditions will also remain, so that if a phosphatic calculus quickly follows the removal of a phosphatic stone by lithotripsy it does not follow that lithotripsy is to blame. If, on the other hand, phosphatic calculus does quickly follow the removal of an acid stone by lithotripsy, it is very probable that either the vesical mucous membrane was injured, became inflamed and offered a rough surface for the deposition of phosphates from the urine, or that fragments and debris were left behind. If lithotripsy be undertaken it must be on the understanding that the operation must be completely finished, every particle of the stone must be removed. For this purpose it will be well to fragment and not to pulverise the stone. Pulverisation has been recommended, but this fine sand or mud is very difficult to entirely remove, it gets entangled in the mucous membrane and attracts phosphatic deposit, while fragments come away easily and are less likely to be left behind in the bladder. If a surgeon has been led by error in judgment to perform lithotripsy in a case not altogether suitable for the operation, and if he thinks he has unavoidably left some particles of stone behind, or, indeed, if he has the least suspicion that such may be the case, I advise that in four or five days after the operation, either with or without the aid of an anæsthetic, an evacuating tube be introduced and an aspirator applied. It will be found that particles difficult to get away at the time of the operation will have become loosened and will come away readily. It is often justifiable to undertake lithotripsy even when all the conditions favourable for lithotripsy are not present. The patient may be too feeble for the surgeon to think him fit to bear incision. In these cases a second or final sitting of lithotripsy to ensure as far as possible the removal of every particle of stone will be a wise proceeding. We thus see that in surgery as, in nature, there are no hard-and-fast lines of demarcation, few absolute rules, and that the rule of modern lithotripsy to remove a stone at one operation has its wise and very proper exceptions. When the stone is very large I am altogether in favour of suprapubic lithotomy. By this incision we have complete command of the bladder, there is little hæmorrhage, the stone is easily manipulated and, if necessary, can be broken up and washed out. The delivery of a large stone suprapubically is not always an easy proceeding. I do not like forceps, which are apt to project beyond the stone, and so unnecessarily tear the bladder. The best instrument is a scoop, placed well under the stone, while the stone itself is steadied by the operator's left forefinger. There are many forceps for breaking up a stone after the bladder has been opened by the knife, and there is no reason why Forbes Keith's giant lithotrite should not be used in this situation rather than from the perineum as practised by him.

India has for centuries offered an unrivalled field for the performance of stone operations and there are surgeons there who can boast of such lists of cases that no surgeon in Europe or America can expect to equal. Dr. D. F. Keegan writes: "We need not look to England or to any country in Europe for guidance"; and it is he who has been chief in establishing as one of the principles of lithotripsy that it is as applicable to children as to adults. Upon his suggestion the smallest tubes and lithotrites have been made, and children of the tenderest years, and even months, are now relieved of their vesical calculi without the knife. Dr. Keegan's teaching, I am satisfied, is as applicable to all as it is to Indian children, but when we come to adults, where the nervous system becomes involved through the sexuality of the urethra, and when the bladder from long-standing prostatic trouble becomes malformed and diseased, then I am satisfied that Indian experience will prove a false and dangerous guide. To paraphrase Dr. Keegan's remark, we need not look to India for guidance. I have been found fault with for speaking of the tolerance of the Indian bladder. I have used the phrase in no carping spirit, for I have sincere admiration for the brilliant work of our Indian surgeons in calculous disorders; but when these surgeons tell us that we make too much of sounding for stone, that it is a trifling affair and needs no special care; when they tell us that vesical pouches and sacculi are easily cleared by the lithotrite of stone and that there is no need to lithotomise; when, indeed, they

attempt to teach us that there is no need for lithotomy at all and that it is obsolete, then I say it is clear to me that they know little of the sensitive European or American and have failed to realise all the vesical troubles of extreme old age. The average stay in hospital of Dr. Keegan's adult cases was only 53 days—far too short a time for safety in England. Dr. Forbes Keith in his interesting paper on the Complete Abandonment of Lithotomy<sup>2</sup> relates such cases as the following. Case 1.—A native, aged 60 years, had his urethra opened by perineal incision. A phosphatic calculus, weighing two ounces, was crushed, and the bladder was evacuated of debris by instruments, some as large as No. 20, passed through the perineal wound. He went home cured on the third day. Case 2.—A youth, aged 18 years, afflicted with a huge vesical calculus, was so ill that after consultation with colleagues it was thought that operation must be followed by death. The urethra was opened from the perineum, a lithotrite was passed through the wound into the bladder, and the stone was seized and broken up by the repeated blows of a hammer. Three ounces of debris were removed and after two hours' work the patient was put back to bed. Four days afterwards the remaining four ounces of stone were similarly attacked and removed in one and a half hours. In three days the patient left the hospital, passing all his urine by the penis and being free from pain. No English urinary organs could be subjected to such treatment and recover in the time mentioned. To English surgeons this vesical tolerance in India is wonderful; we watch and we admire, but we must not be tempted to imitate. I am convinced that if we do we shall push lithotripsy to dangerous extremes and bring it into discredit. Lithotomy will continue to live, it has existed for thousands of years. It is the useful partner, not the jealous rival, of lithotripsy and litholapaxy.

## A Post-Graduate Lecture

ON

### THE ADMINISTRATION OF ANÆSTHETICS IN OPERATIONS ABOUT THE MOUTH, NOSE, AND THROAT.

*Delivered at the West London Post-Graduate College on  
Oct. 21st, 1901,*

By RICKARD W. LLOYD, M.R.C.S. ENG., &c.,  
LECTURER ON ANÆSTHETICS AT THE WEST LONDON POST-GRADUATE  
COLLEGE; ADMINISTRATOR OF ANÆSTHETICS AT THE WEST  
LONDON AND ST. MARK'S HOSPITALS.

GENTLEMEN,—In selecting the title of this lecture the fact that it is the first upon anæsthetics to be delivered as part of the ordinary post-graduate course of this college was overlooked. However, you may consider it a suitable subject of introduction as the cases in this class are among the most painful and ghastly in surgery and are thereby rendered almost inoperable without anæsthesia. They include operations which may immediately and directly save life, such as tracheotomy, and those which may also do so, or at least prolong it, such as operations for cancer in various situations in these regions and some which are for the relief of deformity such as hare-lip and cleft palate. With the advance of knowledge in nose and throat diseases very many operations are now performed which are for the comfort and well-being of sufferers and which no doubt indirectly prolong life. Many are for the removal of obstructions, such as arise from enlarged tonsils, adenoid growths, and abnormal conditions of the turbinate bones. These operations are, indeed, by far the most numerous in this class, and, being operations of expediency the chief danger of which lies perhaps in the anæsthetic, it is impossible to over-estimate the responsibility of the anæsthetist upon whose skilful administration greatly depends the opportunity for the successful conduct of operative treatment.

The administration of anæsthetics in these operations is particularly interesting because often more than one

<sup>2</sup> THE LANCET, Sept. 30th, 1893, p. 800.

anæsthetic and several methods of administration are beneficially called for in the conduct of the same operation, and on account of the various positions necessary during administration and operation. Ether is, no doubt, safer than chloroform, but where any of the operations we are considering takes more than a very few minutes neither gas alone, nor gas and ether, nor ether alone will be convenient during the operation on account of the necessary apparatus being in the way of the operator, and therefore chloroform is frequently used throughout the more prolonged operations or for continuing anæsthesia which has been induced by ether or gas and ether. Either gas or ether, as you are aware, is generally and best administered by what are known as closed methods, and chloroform (the administration of which by a closed method is too dangerous to be practised) should always be given by one or other of several open methods, on which account it is more applicable whenever the supply of anæsthetic has to be continued during an operation upon the nose, mouth, or throat. When ether has been given as a preliminary it is surprising how little chloroform is generally necessary for continuing anæsthesia, and not only is this so but the stimulating effect of the ether makes the administration of chloroform safer than it would otherwise be. The former advantage will be more appreciated by recalling some of Snow's conclusions.<sup>1</sup> He calculated that it was necessary for his second degree of narcotism that the blood of an average adult patient should contain about 12 minims of chloroform; for the third degree, 18 minims; for the fourth, 24 minims; and for the arrest of respiration, 36 minims. In Snow's first degree consciousness is not abolished; there are disturbances of special senses and sensibility. In his second degree the mental functions are impaired, not suspended. In the third degree voluntary movement is suspended, involuntary movement continuing. In the fourth degree the breathing is stertorous, the pupils are dilated, and the muscular system is relaxed; and in his fifth degree the breathing is difficult, feeble, or irregular, sometimes only diaphragmatic, respiration then ceasing and soon the heart also, as in death from asphyxia. The Royal Medical and Chirurgical Committee<sup>2</sup> found that atmospheres containing from 2 per cent. to 4 per cent. of chloroform vapour were attended with little or no risk to life, that 5 per cent. was sometimes necessary, and that stronger atmospheres induced alarming symptoms. Now, when a patient has been anæsthetised with ether much smaller quantities of chloroform need be introduced into the blood to keep up the different stages of anæsthesia than when chloroform is used throughout. Ether causes many patients, especially those with nose and throat disorders, to become very rigid, cyanosed, and more or less congested and swollen about the respiratory passages, and in such cases those symptoms often disappear when the ether is exchanged for chloroform after a few inspirations of the latter, but even in such cases the preliminary administration of ether is an advantage. There are special circumstances associated with these operations that may give rise to respiratory embarrassment, for it may occur on account of the relative positions into which the parts may be placed in the course of the operator's manipulations, or more or less occupation of the air-way by sponges, instruments, the fingers of the operator, blood, mucus, saliva, vomited matters or teeth, especially first teeth in children, that being loose may easily be pushed out of their places by the gag or instruments or fingers; or it may be induced by interference, in the course of the operation, with important nerves that directly influence the performance of respiration and the action of the heart; or by any combination of these conditions.

You may therefore be reminded that the function of respiration is dependent upon a free air-way and is controlled by the respiratory centre which is influenced by all afferent nerves, especially the vagi. The phrenic and intercostal nerves are the chief efferent nerves of respiration. Either excess of carbonic acid or deficiency of oxygen in the blood at first stimulates the respiratory centre but either in greater degree will paralyse it. And the circulation of the blood in the vessels is produced by the heart which is regulated by intrinsic nerves, giving rise to automatic rhythmical contraction, and extrinsic nerves, the latter including a cardio-inhibitory centre in the medulla with its efferent inhibitory

nerves—the vagi—and a cardio-augmentor centre also in the medulla with its afferent augmentor nerves—the sympathetic. The calibre of the vessels is regulated by the vaso-motor centre connected with the vaso-motor nerves—including vaso-constrictor and vaso-dilator—through afferent and efferent nerve-fibres.

The interference with respiration and loss of blood necessarily associated with these operations prolongs the state of anæsthesia and renders a smaller supply of anæsthetic effectual in keeping it up than is necessary when painful operative proceedings are being carried out in other parts of the body while respiration is free or less obstructed. The risk of blood finding its way into the larynx, trachea, and bronchi in these operations makes it very advisable that the supply of anæsthetic should be small to avoid abolishing the pharyngeal and laryngeal reflexes. It is necessary only to supply sufficient to keep the patient quiet enough to avoid interrupting the operator. A patient may be able to move, to mutter, and even to spit without conscious sensation, and it is sufficient to keep up a degree of anæsthesia which just prevents these embarrassing actions. In some cases it is at times difficult to do this even by keeping up a constant supply of chloroform by means of Junker's apparatus through a tube in the mouth or nose. On the other hand, cases more commonly occur in which, with the same apparatus, it is advisable to allow frequent inspirations of air only from time to time, or dangerously deep anæsthesia results.

As long as the degree of anæsthesia indicated as suitable is maintained, the anæsthetist has always, so to speak, something in hand should emergency arise. In other words, the nerve-centres are not so deeply affected by the anæsthetic but that they may rapidly regain control on the relief of obstruction and the better supply of air, and there will be more time to bring about this, the best of all correctives for dangerously embarrassed respiration and heart during anæsthesia. When the centres are being exhausted by excessive hæmorrhage the arrest or control of the bleeding becomes of first importance. As soon as the bleeding ceases the blood-pressure rapidly rises.

We have to consider in any given case the thorough preparation of the patient, especially with a view to prevent vomiting, particularly of solids, which has been responsible for some of the recorded fatalities; the anæsthetic or sequence of anæsthetics to be employed; and the position of the patient during the induction of anæsthesia and during the operation. Local anæsthetics, cocaine or others, suffice for some cases, which cases must be left to the decision of the operator who will wisely be guided by the extent of the operation and the age and temperament of his patient. The application of a local anæsthetic as a preliminary to the administration of gas or other transient dose of anæsthetic is sometimes useful, allowing of a more prolonged operation. Cocaine applied to the throat impairs the laryngeal and pharyngeal sensation, and in excess causes respiratory embarrassment and cardiac failure, so that where it is to be followed by the administration of chloroform it should be used very sparingly and with the greatest caution. The selection of general anæsthetics will depend on the state and age of the patient and the nature and duration of the operation, and any special preference of the operator is to be considered. For short operations, such as the removal of the uvula, tonsils, or adenoids, for turbinectomy, and for the removal of some polypi, gas is sometimes sufficient. Where tonsils and adenoids, both inferior turbinate bones, or numerous or difficult polypi have to be removed gas generally gives insufficient time, and therefore gas and ether, or ether, followed if necessary by chloroform in the manner to be presently described, or chloroform throughout, especially in young children, is advisable. For removal of portions of the lip, the tongue, or either jaw, or similar operations, including tumours in this region, lupus of the nose, deflected septum, &c., either ether or gas and ether followed by chloroform are convenient sequences. Chloroform throughout may be given, especially in operations for hare-lip and cleft palate. Where there is a breach of surface on the nose or mouth the dressing may remain on while the lint, mask, or face-piece is applied, whether chloroform, ether, or gas and ether be used whilst first anæsthetising the patient. In some such cases, as, for instance, extensive removal of the tongue or extirpation of the larynx, the surgeon may consider it expedient to perform tracheotomy as a preliminary, and then with a Hahn's tube in the trachea, or a sponge in the pharynx if an ordinary tracheotomy-tube be used, the difficulties and immediate dangers of the operation are greatly reduced, as blood is

<sup>1</sup> Hewitt: *Anæsthetics and their Administration*, Macmillan and Co., 1901.

<sup>2</sup> *Ibid.*

thereby prevented from getting into the air-passages and the effect of spasm of the glottis, &c., is removed. The administration may then be continued by holding lint sprinkled with chloroform in the neighbourhood of the tracheotomy tube or by means of Junker's apparatus through a tube introduced occasionally into the tracheotomy tube. The administration is thus simplified, as it is not interfered with by any of the various complications which may arise in ordinary cases in the larynx or above it—e.g., spasm, falling back of the tongue, &c.

When chloroform is used throughout until the operation commences it may be given either on lint, a Skinner's mask, or otherwise, but during the operation it is much preferable and often necessary (as lint or other like apparatus would now be in the way of the operator) that it should be continued by means of a Junker's apparatus, the tube being detached from the face-piece and that being replaced by a few inches of gum-elastic catheter or pewter tubing, which is then held in the mouth or nostril, or the tube of the inhaler may be attached to a gag invented by Dr. Frederic Hewitt, which is a modification of Fergusson's gag, there being tubes running parallel with the jaws of the gag through which the chloroform vapour is pumped. When a gag is unnecessary the tube may be passed through the space of a deficient tooth or, if necessary, a prop may be used to avoid collapse of the tube from closure of the teeth upon it. If preliminary tracheotomy has been performed the administration will be continued as just described. If gas and ether or ether has been first used, when the change to chloroform is made at first it may be sprinkled on lint and it may be given in this way, though not very comfortably, throughout the operation, but it is a great advantage to all concerned to use the Junker as mentioned above, and this may be done from the time that the change from the ether is made. Care should be taken that the bottle of the Junker's apparatus is only one-third filled with chloroform and that the india-rubber tubes are correctly applied to the metal tubes, or in using it liquid chloroform instead of vapour may be administered. A fatal result of using the apparatus with the tubes incorrectly applied was once averted by the prompt use of the stomach-pump, tracheotomy, and artificial respiration.

In regard to position, it is usually most convenient to anaesthetise the patient in the ordinary or dorsal position and when ready to change the position to that selected for the operation, in which the convenience and wishes of the operator should be considered as far as possible, and it will often be necessary to vary the position during an operation. In operations for the removal of tonsils and adenoids there are several positions favoured by different operators and anaesthetists, chiefly with a view of avoiding complications arising from the effects of hæmorrhage. In one position the patient is on the side, the pillow having been removed; another is the dorsal position, the head being allowed to fall back over the end of the table; another with the shoulders slightly, and the head more considerably, raised on pillows, &c. I prefer the position on the side with the pillow removed and the face inclined towards the table; there is also some tilting of the head sideways towards the table on account of the shoulders raising the neck in this position, which is an advantage as it also favours the flow of blood away from the air-passages. And, generally speaking, when blood is freely flowing into the back of the mouth I think it a good plan to turn the patient more or less into this position to facilitate the flow of blood from the side of the mouth and the nares. It is generally unnecessary to do any sponging or swabbing out of the blood in this position, while in others it is often imperative. In the position with the head hanging over the end of the table hæmorrhage is encouraged, and there is danger of injuring the cervical spine by undue extension or strain.

For tracheotomy chloroform is preferable, and enough only to keep the patient quiet need be given, especially if the patient is in an asphyxial condition, when it may even be advisable not to delay at all and to operate without an anaesthetic. For the removal of either the tonsils or adenoid growths gas may amply suffice for a dexterous operator; indeed, it may sometimes be possible for him to remove all of these from the same patient under one administration of gas only, but an anaesthetic affording a more lasting anaesthesia allows of a more thorough and satisfactory operation, after which the growth will not be so likely to recur.

No hard-and-fast rules can be laid down as to the use of

particular anaesthetics at different ages, as many circumstances besides age may direct the selection of one anaesthetic rather than another. Generally speaking, chloroform is preferable throughout the operation for children up to six years of age or older. After the age of 10 years, in some cases earlier, gas or gas and ether or ether alone may be administered, and supplemented, if the length of the operation demands it, by chloroform. Often chloroform may be preferred throughout. When gas or gas and ether only are used a prop placed between the teeth before the administration allows the gag to be introduced without loss of time on removing the face-piece of the inhaler. As stated before, the patient should not be deeply chloroformed, and it is often unnecessary to give more chloroform during the operation, which is performed during the several minutes which it takes for the patient to recover sensation. There may be more or less extensive movements of the patient towards the close of the operation, so that a nurse or other assistant should be entirely devoted to controlling these should they occur. The patient should be kept in a position that facilitates the flow of blood away from the air-passages, and the gag should be retained until the patient is sufficiently recovered to be relied upon to prevent blood entering the larynx, &c.

When a cleft palate is being operated upon a firm pillow under the shoulders will allow the head to fall back, affording the operator better access to the region and allowing of the accumulation of blood in the direction of the pharynx and nares. Frequent sponging away of the blood is necessary. Chloroform will probably be used throughout the operation. During turbinectomy it is better to have the patient recumbent to avoid faintness as a result of the loss of blood and for other reasons already mentioned. It is also advisable to keep the mouth open with a gag, and this is so in any operation during which much blood may flow into the mouth or pharynx. In operating for deflected septum if the posterior nares are plugged as a first step much danger and trouble that may arise from hæmorrhage will be avoided. The chloroform is continued by means of a Junker's apparatus, the tube of which is held in the mouth which may be kept open by either a gag or a prop, if necessary. The due performance of respiration should always be looked for. The pulse (which quickens at first during the administration of chloroform and becomes slow when the patient is anaesthetised), will be a guide to the general state of the patient as well as to the depth of anaesthesia, in estimating which the sensibility of the conjunctiva and cornea will assist, and it is always reassuring to observe that the pupil is not dilated.

In the administration of anaesthetics for more prolonged and extensive operations the foregoing considerations should be kept in view and the methods described applied as occasion arises. Avoid danger and complications by inducing only a moderate depth of anaesthesia. By favourable position and sponging, if required, facilitate the removal of blood from the neighbourhood of the air-passages. By holding forward, on both sides if necessary, the lower jaw, this manœuvre will tend to prevent or relieve obstruction of the glottis which may have arisen from falling back of the epiglottis and of the tongue. Should difficulties arise discontinue the anaesthetic and assure yourself on those points; notice, also, the state of the complexion, respiration, pupil, and pulse. If necessary proceed to perform artificial respiration, taking care to have the tongue well drawn out and to perform it slowly—i.e., at about the normal rate of respiration. Laryngotomy may have to be performed, after which operation there is, of course, no need to draw forward the tongue while continuing the artificial respiration, and if a sponge be placed in the pharynx the entry, or further entry, of blood through the larynx into the trachea will be prevented.

After-effects are not generally severe and are modified by the nature, duration, and administration of the anaesthetic; the amount of blood which is swallowed influences the character of the vomit when vomiting occurs.

#### ISOLATION HOSPITAL FOR DEVIZES AND DISTRICT.—

At a meeting of the committee of the Devizes Joint Isolation Hospital held on Nov. 4th it was decided to erect an isolation hospital for the joint urban and rural districts at an estimated cost of £9400.

IMPRESSIONS ABOUT CHLOROFORM AND ETHER.<sup>1</sup>BY SIR WILLIAM MITCHELL BANKS, M.D.,  
F.R.C.S., LL.D.,

SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

So much has been spoken and written upon the subject of anæsthesia that the question seems a very hackneyed one—one that would excite little interest in a society like this. But such is not the case, and such will never be the case while people continue to die under anæsthetics at the rate at which they do at present. During the last 10 years these deaths in England and Wales have just doubled, which is clearly out of proportion to the increased use of anæsthetics in the decade. When there are no more deaths there will be more discussions. But that time, I fear, will never come; for, whatever the drug used, if it can take such a hold upon the nervous system as to produce insensibility to pain and abolish the power of movement, it must be so potent a drug that its use will *ipso facto* imply danger. As regards any discussion which may follow upon my remarks I would hope that it may not be restricted to chloroform and ether alone, for I have only selected these because I cannot speak from great experience about others, while I venture to think that I can about them. When I was a fourth-year student Professor Syme appointed me to be his chloroformist, and for six months I anæsthetised all his hospital patients. After coming to Liverpool I gave chloroform to nearly all Mr. Edward Bickersteth's private patients for six years, and saw all the operations performed at the Royal Infirmary. As assistant surgeon and surgeon to that institution and in my own private practice I must now have seen many thousands of cases of the administration of chloroform and ether. I have been over 34 years in Liverpool. Reckoning 42 working weeks in each year and reckoning that I have seen six cases in each week, the total number seen is about 8500, or nearly one-half of the chloroform and ether cases recorded in the British Medical Association report. I feel sure that you will not think that I mention these facts in any spirit of boastfulness. I do so merely to show that my experience has been sufficient to entitle me to put my own views before you as forcibly as I can. A certain amount of dogmatism is always a good thing, for it arouses the spirit of debate and so the truth comes out. This society of ours is an appropriate place wherein to discuss anæsthetics, for it is interesting to remember that the chemical product termed "chloroform" was first discovered and made by a Liverpool chemist, one Waldie, who managed the Apothecaries' Hall in Colquitt-street; and that Liverpool was probably the first place where the use of ether was extensively practised after having been long supplanted by chloroform in this country. In America ether had always retained its place as the chief anæsthetic and I well remember many years ago Mr. Reginald Harrison bringing to the infirmary an American surgeon, whose name I forget, but who showed us how to use it. He folded up a towel like a cone. Then he took a sponge and saturated it with ether. Wringing the excess of ether out of the sponge on to the floor, he put it inside the towel and stuck it down over the patient's face. We thought this a very wasteful process, and perhaps it was, but it was good sense after all, for it embodied the principle of "Plenty of air and plenty of anæsthetic," and that I believe to be the fundamental principle which underlies all others in the giving of anæsthetics.

## PHYSIOLOGICAL EXPERIMENTS AND STATISTICAL COMMISSIONS.

No one for a moment will consider me as holding in contempt either experiments or commissions as such, and what I say I say with regret, but my firm conviction is that neither of them has hitherto been of the least avail in aiding us in our search for the best anæsthetic or for the best method of using it. What special and particular good came out of the Hyderabad Commission I never could see. There is no possible comparison between a healthy dog or cat or any other animal and a diseased human being. They are not in

the least under the same conditions, and experiments upon them are therefore useless. Take on one side a healthy retriever with its heart and arteries all sound, and without knowledge of what is going to happen to it, consequently without the least fear or anxiety. Take, on the other hand, a middle-aged, somewhat corpulent woman with flabby heart and somewhat inelastic arteries. Suppose her to be the victim of some cancerous disease the knowledge of which has worn her out with anxiety and distress, and then let her pass a sleepless night before the operation, going over and over in imagination all the terrible process and making sure that she will die under the anæsthetic. Or take your drunken, whisky-sodden dock-labourer, with tissues so steeped in drink that one is almost tempted to believe in the possibility of spontaneous combustion, with cirrhotic liver, fatty heart, and albuminous urine. I cannot see any parallel whatever between the healthy canine animal and the diseased human animal, nor can I see how experiment upon the former will help us with the case of the latter. It is impossible. I trust that no lying anti-vivisectionists will take hold of my words and twist them to suit their own ends, as is their wont. For although I honestly cannot see where experiments upon animals have given us direct aid in our quest after securing safety for human beings I am very glad that they have been done. Unless it had been so we should always have remained uneasy under the fear that perchance we might have lost something of value from this source, seeing how much has been learnt from it in other conditions. Moreover, the most virulent anti-vivisectionist cannot complain of any cruelty here, seeing that the animals used have simply slept themselves peacefully and painlessly into extinction.

With regard to the report of the British Medical Association Commission on Anæsthetics, which has recently been made public, one cannot but feel the greatest admiration for the immense pains taken by the members of that body, which came into existence in 1891 and included among its members some of the most eminent men in our profession. One knows, however, as a matter of fact, that in all committees it is the secretary who does the real work. To Dr. Child, the secretary of the General and Executive Committees, and to Mr. George Rowell, the secretary of the Analysis Subcommittee, every medical man (and especially every man who has been a secretary himself) will give unstinted praise for their protracted and laborious work. But at the end what does it all amount to? *Heu! Nil.* In a very able analysis of the report Mr. George Eastes, the treasurer of the Commission, says concerning its conclusions: "The most important conclusion is the last, that by far the most important factor in the safe administration of anæsthetics is the experience of the administrator and that in many cases the anæsthetisation is of such importance and gravity that it is absolutely essential that an anæsthetist of large experience should conduct the administration." As a result of not having discovered anything that we did not know previously I have heard and read of not a little girding at this report. Now, I think that this is not deserved. While it is a great matter to find that certain drugs or methods of treatment are valuable in such-and-such a disease, it is no little thing to have found out that certain other drugs or methods of treatment which looked promising are quite useless. It prevents future investigators going painfully and laboriously over the same ground and it makes us feel comfortable in our minds in the knowledge that one path of information has been looked into, has been found wanting, and is now walled up. But it has been suggested that we still lack an experimental examination of the statement that by proper application of a volumetric method anæsthesia of any required degree can be certainly effected, and that we should carefully determine the percentage of chloroform in the fluids and organs of animals variously anæsthetised. By all means let the inquiry be made. All scientific knowledge is valuable. An investigation, though useless for the purpose for which it was originally intended, has often elicited facts which have proved very valuable for some other purpose. That the investigation now suggested is likely to be of any more value than its predecessors I do not for one moment believe. In the first place, I have stated that I do not think that deductions from experiments on animals in relation to anæsthesia can be used in the case of human beings. In the next place, the simple adage that no two people are alike prevents anything like a uniform treatment being applied all round. We know how the same dose of a drug will act upon various people in the most various ways—how even articles of diet which are

<sup>1</sup> A paper read before the Liverpool Medical Institution on April 25th, 1901.

nourishing and sustaining to the majority of people are practically poisonous to not a few. There are some persons whom the eating of an egg will make very ill. Now alcohol, after all, may perfectly well be compared with chloroform or ether or any anæsthetic. A glass of whisky and soda-water at dinner is a wholesome stimulant to many people and enables them to digest their food, but keep pouring whisky steadily into an individual and he will in time become unconscious, lose his muscular power, and be reduced to a state of anæsthesia. Nay, there are plenty of instances where barrels of spirit have been broached in the street and where unhappy wretches have drunk it to such an extent that they have lain down in the kennel and died poisoned. This is just what chloroform does, only it does it more rapidly. But how can we of set purpose regulate such effects with precision? In the case of a young, frail girl, absolutely unaccustomed to the use of stimulants, a single glass of whisky will make her practically drunk, while a seasoned coalheaver or foundryman will swallow a pint and make no sign. How could we "control the dosage" of whisky to two such people by any rigid physiological application of a volumetric method? So, also, the proper dose of chloroform can only be estimated and regulated by the person who is administering it, and for that he must depend upon his knowledge of the power of the anæsthetic which he is using and upon his judgment, gained by experience, of the ability of the patient before him to inhale certain quantities of that anæsthetic with safety. I am one of those who in things medical place more reliance upon the "impressions" of a sensible man with good powers of clinical observation guided by experience than upon any *a priori* physiological deductions. In June last Dr. Burney Yeo delivered an admirable address to the British Balneological and Climatological Society. He said with reference to the publication some 30 years ago of the Edinburgh Committee's research on the action of mercury on the liver:—

The supposed results of this research were that mercury, so far from increasing the flow of bile, caused its diminution through its general depressing effect on the entire organism, and the reporters added that the practical advantage of demonstrating that mercury is not a cholagogue could not be too highly estimated. Now, gentlemen, what is the teaching of physiologists at the present as to the action of calomel? It is that although calomel does not really cause an increased flow of bile it acts on the bile-exPELLING mechanism and promotes the flow of bile into the intestines. Was more than this claimed in calling calomel a cholagogue? Well, we now no longer hesitate to prescribe calomel for fear of being thought "unscientific." Indeed, calomel is, I should say, nowadays used as extensively as ever it was in the treatment of chronic disease, especially in functional disorders of the stomach and liver.

By which words many persons have doubtless been much heartened and have taken their blue pills and seidlitz powders with a fuller sense of security in their effects. For after all medicine is essentially an empirical art; which brings us back to our simple but all-important keynote, "Plenty of air and plenty of anæsthetic."

#### WHETHER IS CHLOROFORM OR ETHER THE MORE DANGEROUS.

Some years ago there were quite serious disputes as to whether death from chloroform began from the heart or from the lungs. These academic speculations need not trouble us. Be it chloroform or ether or alcohol it is absorbed by the capillaries of the lungs or stomach and is conveyed to all the nervous centres, which in due time it poisons and so abolishes their functions. It both enfeebles the heart and paralyses the respiratory muscles, so that clearly death does not take place from the heart alone or from the lungs alone, but from both. This statement, be it remembered, applies to pure and simple poisoning from an overdose of the drug and not to cases where the patient has died suffocated from his tongue being allowed to fall back.

As to whether chloroform or ether is the more dangerous the physiologists have long been aware that in the case of animals chloroform is infinitely the more dangerous, and therefore in experimental inquiries demanding an anæsthetic they use ether. As for the clinical statisticians, in their report they assign to chloroform a danger-rate of 0.582 per cent. and to ether one of 0.065 per cent., so that according to these figures chloroform is nine times more fatal than ether. But after all surgeons found this out for themselves in a very brief period after the reintroduction of ether into this country. Still, it is a comfort to be confirmed in one's view by the physiologist and the statistician.

Suppose it became necessary for a surgeon to put a person to death by means of an anæsthetic, which one would he choose? There is nobody who would not at once say,

"Chloroform, to be sure"; and the reason is simply this, that up to a certain point chloroform is a depressant, while ether is a stimulant. To discover this you have only to look at the face of the patient and to feel his pulse. Taking chloroform first, let us put aside certain cases where, after a brief period of inhalation, the pulse becomes stronger and steadier. This is due to the fact that the patient before the operation was a prey to serious mental distress and anxiety. When insensibility comes on fear vanishes and the heart works with better will. But, putting these special cases aside, it may be said that as a general rule as the inhalation of chloroform goes on the pulse weakens and the face becomes pale. With ether, on the other hand, the pulse becomes quick and full and the face becomes congested. Ultimately it and especially the ears become livid. In order to get students to grasp these differences I often speak to them of the White Man and the Blue Man. The White Man is being poisoned by chloroform and is always in a dangerous way. His heart is working very feebly and at any minute may give out. The Blue Man, it is true, ought not to have been allowed to become blue, but still he is not in such straits as the other. If he can get a little air into his lungs to oxygenate his blood it will still be very hard to kill him.

#### THE EARLY SIGNS OF DANGER.

With a few exceptions I cannot say that I have ever felt very anxious about the performance of any surgical operation, because I have never been ashamed to beat a retreat in time if things were going against me. But the anæsthetic always has been and always will be to me a serious source of dread. I have therefore always maintained a careful watch on the progress of the anæsthetisation. I believe that there are anæsthetists who maintain that they are supreme in their own place and will not be dictated to by the operating surgeon. Personally, I will have nothing to do with any anæsthetists making any such pretensions. A serious operation is a kind of pitched battle between the surgeon and death. The surgeon is the general; the anæsthetist commands a brigade. If the latter so mis-manages his brigade that the battle is lost, upon whom does the disgrace fall? Upon him? Not for a moment: upon the general, the surgeon. It is he who has to face the dead man's relatives and to explain matters as best he can in the coroner's court. And, when the event is spoken of afterwards, it is not mentioned as having occurred in the practice of the anæsthetist, but in the practice of the surgeon. I therefore hold that, in the matter of the anæsthetic, the surgeon should be master over the management of that, as over every other detail of the operation.

In all polite circles, when any unpleasant statement is made, the company present is always regarded as beyond implication, so I hope to offend nobody here by saying that I do not believe that all deaths from anæsthetics are due to unavoidable causes. After a death from an anæsthetic we are all familiar with the performance that goes on before the coroner and how the jury comes to the conclusion that the patient died from an anæsthetic properly and skillfully administered. In my own experience I have only had two deaths, both from chloroform, and I am quite willing to believe that they were unavoidable. But the number of hair-breadth escapes which I have seen is alarming to reflect upon. In some cases it seemed as if life had really gone and only by the most energetic measures was it brought back—measures which required all one's coolness and fortitude to carry out and which left one utterly exhausted with the mental and bodily strain. I am prepared to admit that in one instance the fault was my own. It was a case of cleft palate in a child where, although the patient was not breathing properly, I yet directed the chloroform to be continued in order that I might get in the last stitch in the uvula. Then came what is called the collapse—that is to say, the patient, not having had enough air for a good while, gave up the struggle. Luckily, the accident was due to the mechanical hindrance of a proper amount of air getting into the lungs and not to direct poison from too much chloroform. With two strokes of a knife I opened the trachea and by squeezing and dilating the chest-wall we got air to enter the lungs and the child recovered. The reports of fatal cases read all alike. They tell how, after the administration of a certain amount of anæsthetic (always astonishingly small, by the way) and occasionally of more or less struggling the patient, with whom everything up to a certain moment has been going as merry as a marriage-bell, "suddenly collapses." This is what I do not for a moment believe. In the

majority of cases he does not suddenly collapse. He has been in a really dangerous way for some time before he collapses, and the real cause of the collapse is the inability of the anæsthetist to recognise the early symptoms of danger and to avert it in time. That is my firm conviction. By anæsthetist I do not mean the special administrator of anæsthetics, so that, should any be here to-night, I pray they will not think that I am delivering an attack upon them. By anæsthetist I mean simply a person—any person—who happens to be giving an anæsthetic. I do not, furthermore, even wish to attach great blame to that person, for I believe that he acts in ignorance, from the fact that he has never been sufficiently trained to recognise the tremendous potency of the drugs he is working with and to know the precise moment when their administration crosses the boundary line of safety and enters the territory of danger. It is not so much his fault as his misfortune. Some men I have seen, it is true, who seem utterly incapable of sniffing danger afar off. It is not in them. They literally cannot see further than their noses. But in this the members of the medical profession are not in any way different from those of any other profession or business. Men enter it who have no real gift or aptitude for it and every now and then such men make serious mistakes, and always will do as long as human beings are what they are. But our business is not to look on at these mistakes and say that they are inevitable, but to strain every nerve to reduce their number. This is only to be done by looking at uncomfortable facts with open eyes and with a determination not to blink them.

#### TOO LITTLE AND TOO MUCH CHLOROFORM.

There is one kind of anæsthetist who has no appreciation of the axiom, "Plenty of air, plenty of anæsthetic." He drains out his chloroform by the drop. Having poured a few minims on the mask, he then pulls up the patient's eyelid and begins fumbling at his cornea; then he feels his pulse and thinks it is very rapid or else getting very weak, and so keeps the surgeon in constant hot water. The patient being now fairly awake gets a little more chloroform and the cornea-fumbling and pulse-feeling begin again. This process goes on for a considerable time until finally, by the time that complete anæsthesia has been attained, the patient has inhaled a large amount of anæsthetic and goes very deeply under. Then he "suddenly collapses." There is another kind of anæsthetist who seems utterly unaware that he is dealing with a poison which of itself will kill if only enough is given. Some patients take their chloroform very quietly with a somewhat shallow breathing. They lie motionless and the operation begins and goes on. All the time the chloroformist keeps pouring on his chloroform, although the patient is deadly quiet, until this one also "suddenly collapses." This variety of chloroformist absolutely refuses to see that when the patient is not feeling pain he should stop his anæsthetic. But he does not. He simply keeps pouring it on and consequently poisoning his patient, for whatever anæsthetic is over and above what is necessary for surgical purposes is poison. I think that the action of some surgeons is in part responsible for this. If the patient comes out and struggles a little many a surgeon gets angry with the anæsthetist. For my own part I always assure him that I will be quite ready to wait till the patient is over again, and meantime he is to play with a light hand. For in truth a great secret is always to keep the patient on the balance: just on the point of coming out. What does it matter if he does cry out occasionally? He will never remember anything about it afterwards and meantime you know that he is alive and well. When he is long deeply under, when he is long silent and motionless, then it is that the silence and immobility of death descend upon him with great suddenness. This steady administration of the chloroform when there is no need for it is a very grave mistake, for it puts the patient in the most critical position possible—viz., that which results from pure uncomplicated poisoning. In those cases, even when the patient has been rescued from immediate death, he will remain for hours and hours in a very dangerous condition, subject to constant relapses. This is because time alone will enable him to get rid of his superfluous chloroform by exhalation.

#### IMPERFECT BREATHING.

There is another condition where the patient is put in great danger—viz., the inability of the anæsthetist to recognise whether the patient is breathing fully and freely or only getting into his lungs a small modicum of air and that filled with chloroform. To kill a dog by suddenly

blocking up its trachea takes about four minutes and it is probably much the same with the human being. It is true that even the most ignorant or careless anæsthetist never completely deprives his patient of all breath for that time, but then it must be remembered that the patient is partially poisoned with the anæsthetic already, and if you annul a large amount of his respiratory action and still give him nothing but anæsthetic to breathe you are keeping him in a dangerous way, so that the form of "sudden collapse"—coroner's court collapse—to which I have alluded, is liable to come on at any minute. It is most distressing to hear a patient going on with this imperfect respiration while the anæsthetic is being quietly piled on and no attempt at relief given. Sometimes the stoppage is complete, and so great are the patient's struggles to get air that his chest-wall moves up and down with the frantic efforts which he is really making to respire, although lying perfectly quiet. Now open his jaws with a gag and pull his tongue well forward and you will hear such a respiration as makes you take a deep breath yourself from mere sympathy. I cannot at all understand the aversion which some people profess to entertain against the use of the tongue forceps. It has been denounced as barbarous and cruel in very severe terms. This is simply childish nonsense. If there is any safety to be got by pulling the tongue out, a little discomfort lasting a few hours should not be considered for a moment. Many years ago the American surgeon, Dr. Howard, in my opinion did a great deal of harm by promulgating the doctrine that pulling the tongue forward did no good. To begin with, I cannot conceive how any man who has once heard the gasp of air given by a patient whose tongue has fallen back and been pulled forward can doubt the efficacy of the process. In the next place, I made several dissections from the side of the neck on the cadaver, noted the position of the base of the tongue and saw how it was pulled up at once by the forceps applied to the tip. There does not seem to be any mystery about the process, except what is made. It is essentially a mechanical affair. The muscles that keep the tongue forward are not very strong. We see that practically when we have divided them in removing the fore-part of the organ, when its base falls back at once and when it is for a while necessary to keep a string in it ready to pull it up in case of the patient choking. It is partially drawn back and partially falls back on to the top of the epiglottis and closes that lid on the box of the larynx. Pulling forward the angles of the jaw does practically the same thing as the forceps, only in a very minor way, but in many cases where I have seen patients in danger from obstructed respiration I have also seen much valuable time lost from fumbling about the angles of the jaw in place of promptly opening the mouth and pulling the tongue well out. Even then some small gags with absurd handles about two inches long are often used with which great difficulty is experienced in getting the jaws apart. I believe that to the anæsthetist far more valuable than all complicated inhalers are a powerful big-handled gag and a first-rate tongue forceps. When the so-called "sudden collapse" has occurred even seconds are of value in getting air into the lungs and so oxygenating the poisoned blood.

#### PERIOD OF STRUGGLING.

A dangerous time in the giving of chloroform is the struggling period. Some persons sink quietly into anæsthesia without a sound or a movement. Others fight and struggle as if they were possessed and during the whole operation seem only to know two stages: they are either so deeply under that they are practically in danger, or out of this state they almost immediately jump into a distressingly lively condition which is a bar to further progress. What volumetric dosage will help us in these opposite conditions where the question is entirely personal to the patient and where the anæsthetist can only trust to his personal experience to carry him through? I think the danger of this struggling period is getting more fully realised now. When I was a student the unfortunate and excited patient was laid hold of by half a dozen dressers and nurses and forced down straight on his back again, while the chloroform was piled on hard by the anæsthetist. Nothing can be worse policy. Look at his contorted cord-like muscles and swollen veins; look at his rigidly clenched teeth, his glaring eyes, and the beads of sweat standing on his forehead. The efforts he is making to sit up are almost superhuman. His heart is almost bursting with its efforts. Let him sit up. He will not be more difficult to manage, but less so, for he

will not fight so much with his arms and legs. Take away the anæsthetic till he has got a few good gasps of air into him and then bring it back but not close down on his face, and as he shifts his head about to get quit of it keep following him with the utmost rapidity. In a little he will probably begin to talk or shout a little nonsense and then sink quietly and safely back on his pillow. I believe that following the old method was the reason why many persons sank back at the end of a struggle on their pillows dead.

#### DANGERS OF CHLOROFORM AND ETHER.

I think, then, that the great dangers of chloroform are: (1) absolute overdosing of the patient up to the poisoning point when there is no necessity for it as regards the operation; (2) an omission to allow the patient to be constantly and freely getting abundance of air into his lungs; and (3) violent repression during the stage of excitement combined with continued dosing with chloroform. Now it may be said that it is surely very easy to watch all these conditions; but it is not, from the fact that there are no two individuals alike as regards the way in which they take anæsthetics, just as there are no two people alike as regards their faces. Out of hundreds of thousands of persons whom one may pass very speedily in a brief time in the streets of a big city and who have eyes, noses, mouths, ears, all fashioned on the same type, we instantly pick out our friends. A good chloroformist rapidly seizes upon the leading features of his patient as regards his capacity for standing the drug and administers the volumetric dosage by rule of thumb, as will always be the case, if safety is to be the main consideration. At the same time, it is impossible to over-estimate the care which should be devoted to a chloroform case during the early periods of the administration. It will be noted that it is nearly always during the earlier periods that the fatalities occur. In the case of a prolonged operation after a while the patient lies quiet, as a rule, and does not need the anæsthetic except at intervals and then a very small dose serves to render him quiet again. There is therefore less likelihood of an unexpected failure of the heart. The chloroformist gets due notice and has time to warn the operator that it is time to wind up, inasmuch as the patient, between them, is quietly but plainly getting weaker. The danger is most between six and 10 minutes from the time the anæsthetic is commenced and during that time the anæsthetist's eye should never be off the patient's face for one instant. The slightest shade of pallor should be noted and the patient should be at once revived; upon the slightest difficulty of breathing his tongue should be instantly pulled out. Were these things done in time the cases of sudden collapse would become wonderfully fewer.

With regard to ether, the great point here is to keep the larynx free from frothy sticky mucus. Some people under ether secrete a vast amount of this from the mouth, fauces, and larynx. This they keep sucking down the trachea into the lungs, which get choked up with it, just as they used to do with blood in former days during operations on the tongue before one began to do a preliminary laryngotomy. Then the patient becomes a Blue Man. But if his jaws be well forced open with a gag and the mucus be swabbed out he recovers. It is to be noticed that among the deaths from ether a few have occurred from pieces of vomited material having been sucked down tightly into the larynx. Surely this is a preventable matter. Moreover, when it has occurred, why have the patients not been saved by a prompt laryngotomy? There are two difficulties about ether. One is that it is neither so pleasant to take nor so easy to give as chloroform, but in consideration of its superior safety these ought not to be so much considered as they are. It ought certainly to be more frequently used. The other is that in certain operations, more especially such as have to do with the anus or urethra, it seems impossible to get the muscular action subdued in certain people by ether. There is nothing for it in such cases but chloroform and that in fullest amount. I am always very fearful about the anæsthetic in operations for hæmorrhoids. But the great point about ether is that it is more difficult to kill a man with it than with chloroform. In both the chloroform fatalities which I have seen the patient was stone dead by the time my attention was drawn to them: face pallid, jaw dropped, and eyes staring wide open with big dilated pupils. You never see anything like that with ether.

#### WHICH MAKES PEOPLE MOST SICK, ETHER OR CHLOROFORM?

I am sure more people are sick under ether, but I am also

sure that when a bad sickness, lasting for a long time, occurs, it results from chloroform. Ice and small mustard poultices over the epigastrium seem to do as much good as anything else.

#### METHODS OF REVIVAL.

To begin with, I do not believe galvanism to be of the slightest use. Furthermore, galvanic batteries are hardly ever in order when required, and even if they are in order it takes too long to get them in action. By the time one of these things gets to work the patient is either dead or in safety again. If with chloroform as the anæsthetic the patient be in danger from overdosing and from having had too little air so that he has been both choked and poisoned we want to do two things—viz., to get air into his lungs and to get blood into his brain. Let someone jump on to the table and hold the patient up by the legs with his head dangling over the end, let his tongue be pulled out, and let Sylvester's method of artificial respiration be resorted to. Slapping with wet towels and many other minor means there are with which everybody is familiar. For some time there have been in use small capsules of amyl nitrite ready to be broken and inhaled. Since their introduction I have never been in such straits with an anæsthetic case as to be driven to use them but I should think that that drug would be of use. I am certain that I have seen good come from subcutaneous injections of ether or strychnine. With ether as an anæsthetic we have noticed that the danger is almost entirely from choking—from the bronchi and upper air-passages getting choked up with froth and sticky mucus. Mopping out the throat and larynx is the great thing here until the patient can be got to retch or to strain and then he comes speedily round. Moreover, his head should not be hung down, but rather the reverse. Failing success with these methods I would open his larynx, get in a tube, and blow air into his lungs while using Sylvester's method also.

But there is a small and very simple dodge which is a very effective means of rousing up a patient from a weak fainting condition if it be used sufficiently early. It is so simple, however, and so devoid of all scientific parade that I do not suppose any high-class anæsthetist could be got to use it. A great many pupils of mine have been taught to use it during many years past and it rejoices among them in the name of the "dry shave." It is known that certain cutaneous shocks induce the respiratory muscles to act—a jump into cold water, smacking with a wet towel. Now when a patient's lips and general countenance begin to get somewhat pale and his breathing very weak, while he makes no sign of movement and lies painfully quiet, if you take a rough towel and rub his lips and nose vigorously up and down with it you will see the colour come into his lips again, his chest will begin to heave, and he will usually make some movements with his head to get out of the way of the rough towel. In short, he rouses up from his fainting state. I know this much from long experience, that if a man does not show any sign of reviving circulation and respiration after a vigorous rubbing of his lips and nose up and down (not sideways) with a rough towel he is in an uncommonly bad way. I have seen a clever anæsthetist keep a most feeble woman safe through a prolonged operation by, so to speak, constantly bringing her up to the surface by this means, and so never allowing her to get too "fainty."

#### PRACTICAL POINTS IN ADMINISTRATION.

As to apparatus the best apparatus is always the simplest. I believe in the simple Skinner's mask, because it allows of most of the face being seen and because, however much chloroform may be poured on it, even until it runs down the patient's chin, there must of necessity always be plenty of air going in with the chloroform vapour. For giving ether men have their own favourite instruments. Ormsby's inhaler and Burton's inhaler seem popular. With my partiality for free admission of air I like the original American one with bandage webbing stretched up and down on a wire frame which is inside a rubber cover. As for those great apparatuses which people wear on their backs (like Parisian lemonade-sellers) or the apparatuses with stopcocks which profess to give regulate quantities of anæsthetics, my notion is that as anæsthetics have to be given in country cottages and in the houses of the poor dwellers in cities as well as in those of the rich, such apparatuses need not be used. The student should be taught to use the simple tools with which he is likely to go into practice. We have tried beginning with nitrous oxide gas and going on direct to ether at

the Liverpool Infirmary, but it does not seem to have found much favour.

Concerning stimulants before anæsthetisation I know that some people object to them because they say that they cause sickness, but this is because they are not given properly. A small quantity of brandy is given in a lot of water about half an hour before the operation. This the patient promptly vomits. The brandy should be neat or with just such a little amount of water added as will enable it to be got down. From one and a half ounces to two ounces for a woman and three ounces for a man is not too much. Let it be gulped down like physic just before the anæsthetic begins, then the patients are not sick. Many a timid, weakly woman after a good big dose of almost raw brandy needs very little anæsthetic indeed. In the pre-chloroform days they made patients half stupid with brandy and laudanum, and it was wonderful how it enabled them to endure pain. I helped once to put in an old medical man's shoulder. He would have no anæsthetic, but went out and got his brandy and laudanum and in about 20 minutes sat down and had the shoulder put in without moving a muscle.

I often give students a lesson. You will see an inexperienced hand jam the inhaler down over the patient's face and choke him. Then the patient fights for life, sits up, and refuses to have any more. The mask should be loaded with anæsthetic as full as it will hold, but it should be held a long way above his face and only brought down to it by slow degrees. Meantime there should be absolute silence everywhere. In private practice nurses seem to delight in fussing and knocking about basins and pots with as much noise as possible, while the surgeon and others are all talking about astonishing cases they have just had. This din excites and agitates the patient, who hears fragmentary sounds and does not know what to make of them. Having got all quiet, I tell the patient to count after me up to 100. A German surgeon showed me how to do this properly. He counted very slowly; then he began to sing the numbers in a drawing tone and finally he performed a sort of chant. I always do this. It seems to lull the patient to sleep, who will often follow the very cadences of the anæsthetist. A large number of persons will cease counting somewhere about 50, if they have had some brandy and all around is silent. I am sure it is far better not to say anything to a patient: it only rouses him up to think.

As to anæsthetics at various ages, I have noticed that infants and very young children get horribly pale under chloroform and have to be carefully watched, but they take it easily, although they often require a great deal. It will be often noticed that boys, say of about six or eight years of age, rapidly fall into a kind of false sleep and look as if they were well over, but if you touch them they shout lustily and kick, so that you have to give them a large amount of anæsthetic, after which they are apt to sink into a very deep sleep, from which they are slow to be awakened.

No bronchitic or asthmatic subject should be given ether and I believe that chloroform is by far the best anæsthetic for very old people. With a little previous brandifying they take it quite sweetly and recover quickly. I have had it given to two males, one 84 and the other 82 years of age, during the past week and nothing could have been pleasanter than the chloroform. Of course, on such very old people only such operations as are speedy of execution and can be done without great shock or loss of blood are admissible and, therefore, no great amount of chloroform is required, but to hesitate about giving it to a healthy old person is quite a mistake.

We always examine a patient's heart before anæsthetisation. It is an odd proceeding after all, for the form of heart disease—dilatation or fatty degeneration—can never be discovered by the usual perfunctory examination we make, and yet it is the dangerous one. Valvular disease, on the other hand, which one can hear, need be very little taken into account. It is one of the conditions under which the pulse, in the early stages of chloroform, seems always to get fuller and steadier. I have often pointed this out to students as an encouragement to them not to fear valvular disease. There is another condition which we are often not aware of, because we do not look out for it—viz., the presence of albumin or sugar in the urine. I suspect that I have perhaps been as guilty as anyone in this matter of not examining the patient's urine before operation in private cases. In hospital this is done for us—or ought to be done—as a matter of routine, and so we get warning. That a man with

albuminous urine and diseased kidneys is a dangerous subject, especially for chloroform, cannot be doubted, and in his case effort should be made to do with the least possible amount of anæsthetic and, if possible, to manage by means of local anæsthesia.

As regards the safest position in which a patient can be placed who has to take an anæsthetic I think that there can be no doubt that the recumbent position on the left side is the safest. The upright position in a chair is certainly the worst and, among other things, has contributed to the many fatalities which have occurred during dental operations. On the other hand, I would be glad to know if any member of the society knows of a fatal case occurring during childbirth. This seems to be a very rare thing, and yet chloroform is constantly being given in such cases. No doubt the patients are mostly at the best and most vigorous period of life, and from their condition may be expected to be in good general health. Also no very deep anæsthesia is required. But I also think that there are two other factors in this immunity, firstly, the fact that the patient lies well round on the left side, and, secondly, the fact that this position is one in which the tongue naturally falls forward and does not impede the breathing.

#### CORONERS' INQUESTS.

If a patient dies during or immediately after an operation there is no coroner's inquest, although there might be one if the coroner chose. But the whole surgical profession would become impossible if their proceedings were to be at the mercy of a coroner and his learned jury, and so the coroner says nothing, but tacitly admits that the operation was done skillfully and in good faith and that death was not the surgeon's fault but the patient's misfortune. I do not see why a death from an anæsthetic should be treated on different grounds. Were the public needing to be protected from reckless treatment it would be a different matter, but to the surgeon and the anæsthetist, in whose practice a death occurs, nothing can be more heartrending and distressing. We are not anxious to cover up any weak points. We are anxious to reveal them to each other and to encourage each other by every means in our power to improve them away. Therefore, there is no need of coroners' inquiries to stimulate us in that direction. But on the other side it becomes a serious question whether it is for the good of the public that the details of deaths from anæsthetics should be inserted in the public newspapers at all. I notice, and every surgeon notices, that when an operation is proposed it is not the operation that is dreaded but the anæsthetic. After a death in this city I have noticed this dread among private patients become distressing. Now, a condition of mental depression and dread is the worst state in which a patient can be who has to be anæsthetised. As the findings of the coroner's court have never contributed in the smallest degree to helping us how to avert danger and as their publication is injurious to the public health I think that the British Medical Association might well bring power to bear upon coroners, so that if a death from an anæsthetic be reported to them they should treat it in the same way as a death from operation and dispense with a public inquiry, unless they have cause to believe that there has been neglect or that the anæsthetic has been given by an unqualified practitioner. I believe that coroners' inquiries have never in this matter saved a human life and have contributed to the deaths of many.

#### WHAT IS THE REMEDY?

I believe, then, that physiological research has not as yet contributed, and in the future is not likely to contribute, to a practical knowledge of the safest way to administer chloroform and ether. I am also of opinion that complicated instruments with valves and stopcocks are not required for their safe administration and that for the most part they cannot and will not be employed in general practice where something very simple is required. Finally, I agree with the report of the British Medical Association inquiry, which stated that, after all their elaborate investigations extending over years, they believed that the safe administration of anæsthetics depended upon the judgment and experience of the administrator. If this be so, how are the administrators of the future being taught? They are not being systematically taught at all. I know that there are schools where the students receive a certain amount of instruction in the giving of anæsthetics, our own being among the number. But it is not enough—sufficient importance is not attached to it. Consider what value is

attached to the teaching of the methods of performing tremendous operations on the abdomen and brain, most of which really save very few lives, and which not one man in 500 who learns about them will ever perform. What an amount of useless biology, anatomy, physiology, and materia medica is stuffed into the student, and simply consumes valuable slices of time out of his five years' curriculum. And yet here is the important subject of anæsthetics, which every student will in due time have to administer, practically passed over as a thing of little consequence, so that many a man gets a diploma who has never once given ether or chloroform. It is time that the schools began to take hold of this matter and to show a practical interest in it, so that the bodies which grant degrees and diplomas may eventually compel the teaching of anæsthetic administration as a necessary part of the student's education.

How is this to be carried out? As regards all hospitals I cannot say, but with regard to those connected with medical schools, I should think that there were very few which at the present day have not an anæsthetist attached to them, and he should be the man to teach the students, every one of whom should be certified by him as having given an anæsthetic to a certain number of persons under his supervision. And, the labourer being worthy of his hire, he should be entitled to a reasonable fee for this. I do not believe in the cry against increasing the expense of medical education. As regards mere fees paid to teachers these are of a most moderate and well-earned character. They amount to little more than half the sums demanded for admission into most of the important businesses and professions; so that my view is that the anæsthetist should do practical teaching in his own important branch and should be properly paid for so doing. I know well that this view has been very ably advanced in the medical press by certain men of eminence who have this subject at heart, and one of the objects of this little paper is, if possible, to give what help it may to their efforts.

## ULCERATION OF THE ŒSOPHAGUS AND STOMACH DUE TO SWALLOWING STRONG HYDROCHLORIC ACID:

LESSONS OF TREATMENT DEDUCED FROM THREE CASES.<sup>1</sup>

By C. B. KEETLEY, F.R.C.S. ENG.,  
SURGEON TO THE WEST LONDON HOSPITAL.

THE main conclusion I draw from a study of these three cases is that in cases of poisoning by the more powerful corrosive acids surgical intervention should be almost immediate and that it is a mistake to postpone resort to surgery until there is no other alternative except that of letting the patient die from inanition. I will give the histories briefly and then discuss the question of treatment.

**CASE 1. Enormous dilatation of the stomach developed after accidental poisoning by strong hydrochloric acid; Loreta's operation; complete relief, apparently lasting; rapid recovery of flesh and strength.**—In the middle of October, 1897, I was asked by my colleague, Dr. J. B. Ball, to see a female patient of his, aged 32 years, who had eight months previously swallowed pure hydrochloric acid by mistake. It was the most striking case of dilatation of the stomach that I have ever seen and it is much to be regretted that no photograph was taken. When the patient stood up, whether she was viewed from the front or from the side, the whole anterior abdominal wall, except in the left iliac region and the extreme right of the right lumbar region, could be seen pushed forward by the stomach. She was very emaciated and the shape and movements of the organ could be seen with ease. There was a difficulty in swallowing and immediate vomiting, which, together with the history of corrosive acid poisoning, suggested either stricture or spasm of the œsophagus as well as of the pylorus. In fact, at this time it seemed almost equally difficult to get food into and out of the stomach.

On Oct. 18th an operation was performed. An incision was

made in the middle line above the umbilicus. The stomach presented. The pylorus could be felt some inches away in the right iliac or lower part of the right lumbar region. No adhesions or signs of thickening of the stomach wall were found. The pyloric portion of the stomach was now "hauled" outside. The word "haul" gives a better idea of the length and size of the organ than would the usual word "pull." Protective gauze packing was employed. A one-and-a-half inch incision was made into the stomach. The pylorus was thickened and was so contracted that it would only just admit the closed blades of a pair of polypus forceps. Gradual dilatation was made, first with the forceps, next with the little finger, and lastly with a three-bladed rectal dilator. With the last the pyloric opening was stretched to a circumference of four and a half inches, and a slight sensation of tearing was felt. Closure of the opening and removal of the dilator were next effected and the stomach was washed out with hot water through the wound. The opening in the stomach and the wound in the abdominal wall were then sutured.

Improvement began at once and progressed rapidly. Indeed, as soon as the patient had fully recovered consciousness after the anæsthetic she felt well and complained of nothing afterwards but an inordinate appetite. Vomiting ceased and the patient rapidly put on flesh. A year afterwards she was in good health and strength. The stomach never quite returned to its normal size. Last year I heard that she had not been so well recently, but I did not learn what was the matter. She has left her former address and I cannot find her, so I cannot report on her present state. The patient was shown at a meeting of the West London Medico-Chirurgical Society in December, 1897. I cannot remember who was the medical friend who saw her last year; but if he sees this I hope he will communicate with me.

**CASE 2. Suicidal poisoning by strong hydrochloric acid; rapid development of bronchitis and obstruction to breathing; extreme weakness; abdominal incision, but the stomach not opened on account of sudden collapse; great temporary improvement for 10 days; death three days later; contraction of the pylorus and pneumonia.**—The patient, a man, aged 25 years, was readmitted into hospital on Oct. 19th, 1897, the day after the operation on the patient in Case 1. He had been first admitted under the care of Dr. Hood. 32 days before his first admission he had swallowed strong hydrochloric acid with suicidal intent. After passing 18 days in the hospital he was discharged. He had then no pains, there were no physical signs of illness, and he "could swallow thin foods and milk." Very shortly after leaving he began to lose flesh, found difficulty in swallowing even liquids, and at last "what food he did swallow was vomited." When he was readmitted there was a "constant feeling of sickness" and the patient was emaciated. There was no ulceration or cicatrization of the mouth or the fauces. He could not swallow saliva. Attempts to pass œsophageal bougies caused much distress and induced vomiting. There were signs of pyloric obstruction. The greater curvature of the stomach descended an inch below the umbilicus. Palpation caused slight pain and excited spasmodic contraction. No thickening could be felt. The vomit for the most part was liquid and very dark brown. Constipation was present. On Oct. 21st rectal feeding was commenced. On the 28th when I saw the patient, as he had been getting more and more emaciated, I recommended operation. I noticed that he was then suffering from some bronchial or pneumonic affection with expectoration of copious blackish phlegm.

On Oct. 29th operation was proceeded with. I made an incision to the right of the middle line. The pylorus was exposed, but before further steps could be taken the patient became collapsed and blue. It was considered necessary to postpone opening the stomach. Iodoform gauze (wrung out in 1 in 2000 sublimate lotion) was placed in the wound so as to prepare for a future second stage of operation, without anæsthetic, in a day or two. A few ounces of neutral saline were injected subcutaneously into the axilla and 14 ounces of warm milk into the rectum. A urethral bougie was passed down the œsophagus. My intention, as may have been inferred, was to enlarge the pylorus without a general anæsthetic about 48 hours after the unfinished operation, but a curious change in the patient prevented me. "He was much better in the night and for the first time for eight days was able to take fluid by the mouth." For the next 10 days he took milk freely and improved in strength and spirits every day. But unfortunately on the eleventh day a good deal of pain was complained of in the right side. On the

<sup>1</sup> A paper read before the Royal Medical and Chirurgical Society on Nov. 12th, 1901.

thirteenth day the note is: "Better night. Kept expectorating dark-coloured phlegm. Very collapsed in morning. Very little pulse. Gradually sank and died." The temperature had ranged from 97° to 98.4°F., rising only one degree the day before death.

The only observations noted post mortem were pneumonia of the base of the lung, congestion, and possibly a stricture of the upper part of the œsophagus, thickening and a very tight stricture of the pylorus, and enormous distension of the stomach.

It is difficult to be sure of what occurred in this case after the incomplete operation. Possibly the passage of the urethral bougie down the œsophagus restored the power of swallowing, but as the pyloric stricture remained unrelieved less fluid passed out of than into the stomach, and so the gastric dilatation increased and the general condition became more dangerous. I was lulled into a false sense of security by the improvement in the patient's spirits and appearance. (The notes of the case were taken by Mr. J. M. Flavelle and Mr. A. Granville.)

**CASE 3. Suicidal poisoning by strong hydrochloric acid; stricture and progressive ulceration of the œsophagus and of the pyloric part of the stomach as well as of the pylorus; great emaciation and depression; gastro-enterostomy with Murphy's button; immediate relief and continued improvement for nearly six weeks, then death from bronchitis and pneumonia; Murphy's button found in the stomach, and the ulceration of the œsophagus unhealed.**—The patient, a female, aged 46 years, was admitted under the care of Dr. Hood on Sept. 13th, 1900. When under the influence of drink she had attempted suicide with strong hydrochloric acid. She had "spat out most of it." The mouth and the fauces were burnt by the acid. There were pain all down the throat and in the stomach and great thirst. An emetic and then bicarbonate of potash and calcined magnesia were administered. The pulse was 104 and of good volume and tension. For 10 days she had pain and the vomit occasionally contained blood. Compound mixture of bismuth with glycerine of carbolic acid (10 minims), was given internally, and chlorate of potash gargle. The mixture seemed to remove both the pain and the vomiting. Nutrient enemata were employed. On the eighteenth day (Sept. 30th) the mouth and lips had healed. On Oct. 1st milk was given by the mouth. On the 9th the nutrient enemata were stopped. The patient took more by the mouth; there was great hunger. Swallowing, unfortunately, became more and more difficult. Before the 27th (the forty-third day) scarcely even the smallest quantity of liquid could be swallowed. Emaciation and weakness were extreme. The nutrient enemata had been renewed on the 23rd.

On Oct. 27th operative measures were carried out. A median incision was made. The pylorus presented at once in the middle line, but could not be turned out owing to extensive and tough adhesions. The incision was prolonged up to the xiphoid. The left rectus and superjacent skin were cut through transversely. Extensive, strong adhesions of the stomach to the omentum, the abdominal wall, and the transverse colon were partly clamped and were all divided or separated. The stomach could then be moved. The pyloric portion was contracted to the shape of a small sausage; the cardiac end was smaller than natural and almost entirely under the left costal margin. An anterior gastro-jejunostomy with a Murphy's button was performed. The bowel and the stomach apertures were tightened round the halves of the buttons by two or three interrupted fine silk sero-muscular sutures. The contracted pyloric part of the stomach was three or four inches long. Its lumen would not admit the tip of the little finger—in fact, it seemed almost impervious. The parietal wound was closed in layers. There was no drain. The patient was very collapsed after the operation. The pulse in the evening was 176. The nutrient enemata were not retained. Milk and hot water (in equal parts) were therefore given by the mouth at once. Five ounces were given—one ounce every quarter of an hour. This was repeated in the evening; there was no vomiting. The patient's condition improved. On the 28th (the day after the operation) the pulse was 112. Liquid food was retained both by the stomach and by the rectum. On the 30th the patient was better still; the pulse was 90. She vomited altogether three times in the course of the first 10 days. On the tenth night she retched a great deal. There was no abdominal tenderness. Did the Murphy's button fall back into the stomach at this time and cause the retching? Feeding by the mouth was stopped for 24 hours and then was

resumed cautiously with milk and "Valentine." There was no more vomiting. The wound healed. The patient increased in strength and cheerfulness. The temperature was normal till Nov. 20th (the twenty-fifth day after the operation), when it began to rise gradually, and on the twenty-nine day it reached 101.6° F.; it only once reached 102° (four-hourly chart). With the rising temperature was noticed a slight cough with mucous expectoration. There was no pain or tenderness in the epigastrium. Some pain over the base of the right lung continued and there were occasional paroxysms of pain in the "left iliac region." Was this caused by the button, which x rays had a week before shown to have probably fallen back into the stomach? There were râles on coughing, but there was no dulness at the right base. On the 24th the mucus was slightly rusty; the chest was tender when percussed. On the 29th the sputum was offensive, muco-purulent, and more copious. On Dec. 2nd (the thirty-ninth day after the operation) the patient could not swallow solid food. On the 4th the diarrhoea which had been present for the last three days still persisted. On the 5th the patient died from collapse.

The post-mortem examination showed a stricture two inches long, scarcely admitting a lead pencil, at the upper extremity of the œsophagus. At the cardiac end was a second stricture, less tight, but with ulceration still active. The Murphy's button was free in the cavity of the stomach. The ulceration had quite healed. The cicatrised and contracted pyloric end had further contracted longitudinally to about half its length at the date of the gastro-enterostomy (six weeks before). A narrow curved or sinuous passage led through it into the duodenum. The gastro-enterostomy was perfect with a free passage into the distal loop of the jejunum, and a narrower one into the proximal. The extensive adhesions observed at the operation had nearly all disappeared and nothing remained to interfere with free movements of the stomach. The large bronchi were ulcerated and contained foul purulent secretion. There was grey hepatisation of the left lung throughout. Some pneumonia was present at the base of the right lung. (The notes of the case were taken by Mr. Bennett and Mr. O. Inchley.)

#### REMARKS ON THE THREE CASES.

That which was least injured and non-suicidal recovered but passed through a period of illness which if left unrelieved must have had serious consequences. Both suicidal cases were much worse than Case 1 at the time of operation. Besides, in both cases the bronchial trouble began before operation. In Case 2 the following note was recorded the day after the acid was swallowed: "Large mucous râles all over chest, back and front." Two days later there is the note, "Respiration, especially at night, is very noisy and sounds as if it was obstructed." The note on the day of his discharge is, "Lungs practically clear"; it continues: "No sickness, no dysphagia, no," &c. Nevertheless, this patient had to be re-admitted in 14 days worse than ever. There is no note about his respiratory organs on re-admission, probably because attention was concentrated on his serious œsophageal and gastric troubles. The patients in Cases 2 and 3 did not suffer to anything like the same extent as did the patient in Case 1 from gastric dilatation; indeed, the third patient had a stomach much smaller than normal. But they were more seriously injured in the œsophagus. A careful post-mortem examination of that organ from Case 3 persuades me that its ulceration was still progressive rather than healing, although her death occurred 40 days after operation and 83 days after swallowing the corrosive acid. In both the fatal cases the patient died from septic broncho-pneumonia; I see no reason for attributing this to the operations. In Case 2 nothing was done but the making of a small incision in the abdominal wall. In Case 3 healing was rapid. A post-mortem examination showed the gastro-entero-tomy to be perfect, and not only was there no peritonitis but most of the adhesions seen at the operation, 40 days before, had been absorbed.

I believe the ulceration of the œsophagus or of the pharynx leads to the infection of the air-passages. This may occur directly through the lymphatics, or indirectly through the passage of muco-purulent discharge downwards through a glottis, perhaps itself œdematous or thickened, or otherwise impaired by the action of the acid, not necessarily on the glottis itself, but on parts closely adjacent to it.

At the same time the physical strength and the mental and moral state of such patients are lowered extremely by

both the causes and the results of the accident. The utmost conceivable depth of "lowness" is reached by a patient who, as a consequence of swallowing a corrosive acid suicidally, is for a long period neither able to pass food through the œsophagus nor chyme through the pylorus.

#### THE QUESTION OF TREATMENT.

These cases seem to me to teach certain lessons. Conclusions should be drawn cautiously from a short series of only three cases; but the rules which I am going to lay down are indicated by these cases, not only collectively, but individually. It is not, therefore, a mere matter of statistics.

1. The patient should receive no food (either liquid or solid) by the mouth for several weeks—i.e., he should not be fed by the mouth as soon as he can swallow with little or no pain; but oral feeding should be postponed until there is good reason to believe that the injuries have completely healed.

2. When the injuries are serious (and they generally are so) an operation should be performed within a few days of the date of the poisoning—the sooner the better.

It must always be a matter of conjecture to determine whether the injuries have healed or not. The only parts of the injured tract visible are the mouth and pharynx, but the pylorus or even the middle of the stomach may be much worse, as, e.g., in Case 3, not to mention the œsophagus. In Case 3 the mouth and lips are noted as having healed on the eighteenth day, but active ulceration of the gullet was found after death on the eighty-fourth day (three months after the accident).

I am afraid that it is rarely safe to assume that a case of this kind is not serious unless it is positively known that only a minute quantity of acid has been swallowed. Case 3 was scarcely a truly suicidal one. The patient got drunk on the "rent money," was scolded by her husband, drank the acid, but spat most of it out again; she was brought to the hospital and made to swallow calcined lime and an emetic, and yet her injuries were terrible. Even when swallowed by pure accident an ounce or more is easily taken into the gullet before the mistake is discovered and most of it passes into the stomach, running along the lesser curvature till it is stopped by the pylorus or by food already in the stomach.

All the three cases were treated according to what seems to be the usual practice—that is, the patients were allowed to swallow food when they could do it without much difficulty or pain. The patient in Case 2 was fed by the mouth from the very first day. The subject of Case 3 began with milk on the sixth day and took puddings on the fifteenth day. She never got as far as fish or meat. Granting that the patient should not be fed at all by the mouth for several weeks, and that we should only be satisfied with rectal feeding in trivial cases, the severe cases remain to raise the question of operative treatment.

The region most seriously injured is usually the pyloric part of the stomach. The problem for the surgeon's solution is not simple. The choice of operations apparently lies between gastrostomy, duodenostomy, jejunostomy, gastro-enterostomy, and a combination of gastrostomy with gastro-enterostomy. Gastrostomy does not give rest to the most injured part—namely, the pylorus. Gastro-enterostomy does not rest the œsophagus. Jejunostomy, when properly done, is practically a double operation. Duodenostomy would seem to be the simplest and most straightforward procedure, although it is liable to permit bile to leak out and irritate the skin. All these methods are open to the objection that, in the by no means unlikely event of an œsophageal or a pyloric contraction taking place after all, a secondary operation may have to be done, in addition to one for undoing the first operation. Therefore the indications would most likely be best met by combining a gastrostomy with a gastro-enterostomy, and carrying the gastrostomy tube through the gastro-enterostomy wound for some distance down the efferent loop of the jejunum. This is practically the method recommended by Witzel for an ordinary gastro-enterostomy, except that in the cases I am writing about something more is desirable—viz., an arrangement for washing out and draining the stomach through the gastrostomy wound. This could be obtained either by using a double tube, especially constructed so that the shorter canal opened into the stomach, or, more readily, by passing the long, narrow gastro-jejunal tube through a short, wide gastric tube. In spite of treatment pyloric contraction should take place this plan provides a gastro-enterostomy ready made. The gastrostomy wound could

be closed or kept open, according to the final condition of the œsophagus. In the hands of careful and experienced operators the method would probably be found very safe, as the patient would be operated on while in fair physical condition, and the gastro-jejunal tube should resist the dangers of the "vicious circle." These dangers could be further minimised by using Murphy's button, and, should that contrivance fall into the stomach, the gastrostomy wound itself could be enlarged to permit its extraction. Further, the treatment above recommended would reduce to a minimum the danger of infection of the air-passages, through the swallowing or the regurgitation of septic discharge, or of food, either of which might easily find its way through a glottis œdematous and stiffened either by direct injury or by injury to neighbouring parts. In a long series of cases of poisoning by corrosives now and then the glottis is likely to be so severely injured as to demand prompt tracheotomy. This would make it more than ever desirable not to feed by the mouth.

At the post-mortem examination of Case 3 I was struck by the resemblance of the ulcerated bronchi to those of a case in which bronchial infection and gangrene had been caused by a tracheo-œsophageal fistula.

#### AFTER-TREATMENT.

Feeding by the gastro-jejunal tube would be commenced at once, in spite even of moderate ether or chloroform vomiting, should those anæsthetics be used, but gas alone, or with oxygen, would suffice for the operation described, or even local anæsthesia. Local treatment should be given to (1) the mouth and nose, (2) the pharynx and the œsophagus, and (3) the stomach.

*The mouth.*—This should be frequently washed out with warm solution of chlorate of potash or warm boric lotion, or with both. Dirty teeth should be cleaned, diseased teeth should be treated with pure carbolic acid or by extraction, and suppurating alveoli should be attended to. If the process is very painful owing to the burning, gas, cocaine, or eucaine should be used. The nasal passages should be attended to if unhealthy; if healthy they should be left untouched.

*The pharynx.*—The pharynx is said not to be reached by gargles. It should be sprayed frequently with hot boric lotion, and twice a day it should be dusted with a little, not much, iodoform powder through a puff. As soon as the patient can swallow without pain he should be allowed hot water or hot neutral saline *ad lib.*, and be encouraged to take it.

*The stomach.*—The hot water swallowed should be allowed to escape by the short gastrostomy tube, so that it would tend to wash out the stomach also. In addition, after each meal given by the gastro-jejunal tube, the stomach should be washed out with hot water by the gastric tube.

The application in some such way as that above sketched of the principles of surgery to this distressing class of cases would, I believe, greatly reduce their mortality and lessen the permanent injury done to those who more or less recover.

Grosvenor-street, W.

### NOTES OF A SEVERE AND LONG-STANDING CASE OF LUPUS TREATED BY THE APPLICATION OF THE X RAYS.

By GEORGE H. RODMAN, M.D. DURH., M.R.C.S. ENG.

THE patient whose treatment is the subject of the following notes is a woman, aged about 33 years, who has suffered from lupus of the face, which is reported to have started after an operation for the removal of a diseased portion of the left malar bone some 20 years ago. There is a history of tuberculosis in the family, one sister having died from phthisis at the age of 14 years, and a brother also was the victim of laryngeal phthisis. The lupus had been scraped about 15 years ago; since then it has been treated medicinally and by the local application of ointments and lotions. At the time of starting the treatment by the x rays, on April 19th, 1901, when Fig. 1 and Fig. 2 were obtained, the disease was involving both sides of the face, the ulceration being continued under the chin. On the left side of the face the disease extended from the zygomatic

arch over the cheek and involved the lobe of the ear which was considerably eroded from lupoid ulceration. Anteriorly the disease extended to within half an inch of the angle of the mouth. The upper portion of this area was covered with dry brownish scabs, the lower half being smoother and less ulcerated. The edges of the disease were considerably

the same time it caused frightful disfigurement and presented the features of typical lupus.

The x-ray treatment was commenced on April 19th, 1901, and between that date and July 29th, 1901, when it was

FIG. 3.

FIG. 1.

raised and indurated. Below the jaw the disease consisted of a strip of about an inch in width extending from the ramus of one side to that of the other; the scabbing was chiefly about the edges. On the right side of the face the disease was slightly less extensive than on the left, but at

Showing the condition of the patient, left side, on Oct. 6th, 1901.

FIG. 4.

Showing the condition of the patient, right side, on Oct. 6th, 1901.

stopped, there were 50 exposures made, of which details are given in the accompanying table. 14 were employed in

dealing with the left side on the first occasion. 17 were used to the right side, and on the second occasion of dealing with the left side there were 19 exposures made. On Sept. 13th, 1901, the healing process was complete with the exception of a small patch on the lobule of the left ear which it is my intention to expose again on some future occasion to the influence of the vacuum tube.

During the early sittings it will be noticed that the length of the exposures was shorter and the distance of the tube from the disease greater than that employed later—a course that should be invariably followed till the tolerance of the patient has been ascertained. Six applications were employed weekly during the period of active treatment.

The x rays were produced, as will be seen from the table, with a potential of about eleven and a half volts, and the amperage employed was between two and three amperes in the primary current.

The tube used was a Cox's record tube excited by a 10-inch coil with platinum break. The portions of the face and neck not affected by the disease and the scalp were protected from the influence of the rays by a paper pulp mask, the outer surface of which was covered with a layer of thick lead foil. No falling off of the hair of the head or the eyebrows was noticed. Fig. 3 and Fig. 4 were obtained on Oct. 6th, 1901. These, as well as those before treatment was commenced, are from unretouched negatives kindly taken for me by my friend Mr. Albert Cheese. In Fig. 3 the dark discolouration of the left cheek over the seat of lupus has been exaggerated in the photograph.

#### REMARKS.

April 19th.—The application of the x rays to the left side of the face was commenced.

April 28th.—The lobule of the ear was showing signs of irritation and was becoming raw from separation of scabs, consequently it was protected with lead-foil.

April 29th.—The whole surface of the left side of the face was becoming redder.

May 1st.—Discharging pus in several points.

May 5th.—The patient complained of the surface being very tender. The lupus nodules at the upper and front edge were suppurating. The whole area looked flatter and there was not nearly so much infiltration of the edges.

May 6th.—The surface was discharging pus freely and the crusts

were separating; it was very tender and sore. The application of the x rays was discontinued.

May 11th.—The crusts had come away, leaving a clean, suppurating, raw, smooth surface resembling a burn in process of healing.

May 21st.—There was a white edge of healing ulceration round the raw surface. This edge varied in width from one-eighth to one-quarter of an inch. In several spots there were islands of white healing centres.

May 26th.—The healing process proceeded rapidly, the white edge increasing in width. There were some remains of tubercular nodules at the extreme front.

June 2nd.—Continued to heal rapidly.

June 3rd.—Treatment was started on the right side of the face.

June 5th.—No reaction was noticed.

June 6th.—There was commencing hyperæmia of the ulcerated surface.

June 10th.—The healing process on the left side continued to progress satisfactorily.

June 16th.—The patient complained of the right cheek becoming sore. The surface began to look glazed. The healing of the left side of the face had continued uninterruptedly, and there was now only a small patch of ulceration in the centre of the size of a three-penny-piece.

June 20th.—Tenderness was more marked and suppurating was commencing.

June 21st.—The crusts had separated and the surface was freely suppurating. The application of the x rays was stopped.

June 25th.—The surface of the right cheek resembled that of a healing burn, the whole of the lupoid tissue having suppurated.

July 6th.—The surface had continued to suppurate freely and was now healing with a typical white edge extending over a smooth red raw surface.

July 8th.—Treatment was reapplied to the left side of the face; a mask of lead-foil was applied over the parts cured and the rays were only allowed to invade the front edge of the scar, a patch over the zygoma, and the lobule of the ear.

July 12th.—The lobule of the ear was becoming slightly tender.

July 15th.—The ear was still tender, but at present there was no appearance of swelling of the lupoid edge on the cheek.

July 18th.—The ear was discharging freely, and consequently it was masked with lead foil.

July 22nd.—The ear was discharging freely; the edge of the scar on the cheek was becoming raised and tender.

July 25th.—Crusts were forming and becoming raised and the discharging ear continued very tender.

July 28th.—The crusts were commencing to separate.

July 29th.—The edge had become raw and suppurating. Application of the x rays was discontinued.

Sept. 13th.—The patient was completely healed.

East Sheen, S.W.

## A CASE OF LUPUS VULGARIS TREATED BY EXPOSURE TO X RAYS.

By T. COKE SQUANCE, M.D. DURH.,

PHYSICIAN AND PATHOLOGIST TO THE SUNDERLAND INFIRMARY; ORAL EXAMINER IN PUBLIC HEALTH IN THE UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

ON July 15th, 1900, I was consulted by a woman with regard to her daughter, aged 17 years, who had suffered from lupus vulgaris for upwards of two years, during which period she had been on two occasions treated by erosion but without any permanent benefit, the disease having returned with increased virulency. Fig. 1 gives a very good idea of the appearance of the patient. Her nose was very much thickened and the alæ were ulcerating. The upper lip was extremely swollen, measuring a little over an inch from the skin to the mucous membrane. The disease extended over both cheeks, affecting the lower lids of both eyes. There was a patch on the forehead (concealed by the hair) and a large one extending over the angle of the jaw on the right side. I advised, as other methods had failed, that exposure to the x rays should be tried. This was agreed to, and at first I gave the patient 10 minutes' exposure three times a week, protecting the eyes as far as possible but allowing the lower lids to be exposed. After the first exposure there was decided flushing, accompanied by some pain and tingling and a sensation of heat which continued more or less markedly after each sitting, the skin assuming a reddish-brown appearance with yellowish crusts. As soon as the installation of the x ray apparatus at the Sunderland Infirmary was effected she became an inmate of the infirmary, and the subsequent exposures to the rays were made by Mr. S. S. Lacombe (who had charge of the apparatus). For some time the exposures were made daily until the reaction became so marked that the treatment had to be intermitted, and the eyes also required attention, cornetitis having supervened. Improvement was steady but slow until the condition shown in Fig. 2 was achieved, when the patient was practically cured, but as a precautionary measure occasional

exposures are still made. On account of the patch on the forehead no proper protection could be given to the hair which became considerably thinned.

The distance of the tube was varied from seven to three inches and the length of exposure from five to 15 minutes. It is somewhat difficult to account for the action of the rays

Condition of patient on July 15th, 1900.

FIG. 2.

Condition of patient on July 20th, 1901.

in lupus; probably it is a dual one, on the one hand by excessive stimulation of the bacilli, causing "over population" and consequent dearth of food, and on the other producing an inflammatory reaction in the healthy tissues on the margin of, and below, the diseased portion, causing them to put on an increased resistance.

Sunderland.

## ROTATION OF THE FOREARM.<sup>1</sup>

BY RICHARD J. ANDERSON, M.D. R.U.I., M.R.C.S. ENG.,  
PROFESSOR OF NATURAL HISTORY, MINERALOGY, AND GEOLOGY,  
QUEEN'S COLLEGE, GALWAY.

PROFESSOR HEIBERG of Christiania has called attention to the fact that the movements of supination and pronation are commonly attributed to the motions of the radius alone. He has shown that in addition to the movement of the lower end of the radius round the ulnar styloid process (the pit at the root of the styloid process) the ulna moves too; both bones near the wrist move along curves. Heiberg made his views clear by models and made experiments to confirm the results. His conclusions were embodied in a paper read before the Copenhagen International Medical Congress. The presumption that the humero-ulnar articulation does not admit of any movement except flexion and extension led to the suggestion that the humerus rotated and not the ulna. The movement of the ulna, however, took place after the humerus had been clamped. Then it was shown that the forced twisting of the hand was not necessary to establish the facts. Dr. Cathcart of Edinburgh showed by means of a ring that the ulna moved under the bracelet as clearly as the radius. A demonstration was given at a meeting of the British Medical Association. A frame with an upper and a lower clamp with an intermediate graduated circle was used to test the amount of rotation at any part of a limb for a given displacement at the distal end. The latter, being determined by means of a graduated circular scale, was read off and the corresponding number on the intermediate graduated circle was noted.<sup>2</sup> The degree of rotation was ascertained in the anterior limb of several animals. Rotation becomes less and less conspicuous as we proceed to examine the forearm nearer and nearer the elbow-joint, and in man a slight displacement of the bones indicates what remains of movement at the limit. The following method may be used to show the rotation of the arm. An elastic band with a buckle is attached to a mirror three quarters of an inch wide. This band is fixed over the lower end of the forearm with the mirror over the styloid process of the radius first and afterwards over the styloid process of the ulna. Except in extreme supination and pronation the mirror may be made to follow the rotating wrist. A beam from a lantern with reflector allowed to fall on the mirror will show the nature of the rotation. The band can be gradually moved upwards, and at each stage the rotation tested; where the mirror rests on a bone the tilt will render more conspicuous the movement. This contributes chiefly to produce the deviation of the reflected beam when the mirror is placed over the olecranon. The roll here, though slight, is felt by the mirror.

The intimate connexion between movements, ligaments, and articulations has long been established, indeed, since the time of the appearance of the works of Henle, Cruveilhier, and C. Krause. Leaving out all those articulations in which surfaces are difficult and in which the movements are correspondingly complex, there still remains an assortment of articular surfaces which anatomists have tried to group and classify, and to which nature has assigned certain varieties of ligaments and has associated certain movements. Inter-articular cartilages and ligaments render joints confusing, and it is only by referring to the conditions in the lower animal forms that one can hope to get an explanation of the odd conditions in man. The peculiarity of the hip-joint was only understood after comparative anatomical investigation (W. Krause). The condition of the ulna is only understood after referring to the development of the articulation and its condition in other animals. The fixed radial head in the sheep is seen to supplement the coronoid portion of the ulna in rendering more secure the elbow-joint; the elongated hollow of the articular head of the radius in the badger is intermediate in form, but the head of the radius in man is not strictly circular.

The joints in the forearm are somewhat varied. Leaving out the wrist-joint, the lower radio-ulnar articulation is made up of surfaces of the second order (hyperboloid). The same holds for the upper radio-ulnar joint. The articular hollow in the upper end of the radius is apparently a hollow sphere,

<sup>1</sup> A paper read before the British Medical Association, Surgery Section, on August 1st, 1901.

<sup>2</sup> Anatomische Anzeiger, 1892.

but in all probability rarely so simple, and it may be limited to a portion of the head, whilst a portion becomes flat or slightly convex. The convex articular surface of the humerus, limited to the anterior and lower part, passes internally into the ulnar articular surface. This capitular surface registers the imperfect attempt of nature to make a ball-and-socket joint. The easiest form of glass lens to make is, we are told, a spherical one, but the conditions are different where the surfaces are living. The ulna has really two humeral joints which were at one time separate in man, the interval being occupied by fibrous synovial processes; at birth there is a simple joint. The surfaces are hyperboloid running into spherical externally and paraboloid or ellipsoidal internally; the surface is sometimes called helicoid or screw surface.<sup>3</sup> The olecranon articulates above behind and below, the coronoid process in front and below. The surface is not a hyperboloid of one sheet as a straight wire does not lie in the surface. The hollow inner part of the coronoid articulation is greater than the hollow inner part of the olecranon (a well-known fact). The shapes of the bones which give us a key to form, as the joints give us a key to motions, are in their constitution influenced apparently by the part they take in bearing strains and by the vascular supply. It is not easy to say whether the lines of the trabeculae in the cancellous tissue are chiefly the cause of the shapes of the articulations or are altogether the result of the intermittent pressure produced by the bones. The radiating fibres suggest a response to the lines of pressure.

The motions of the bones concerned in rotation of the forearm are that of the radius on the ulna, that of the ulna in relation to the radius, and that of each in relation to the humerus. The radius would describe a cone-like surface if the ulna were fixed and the head circular. The radius follows, however, the moving ulna as a satellite follows its planet. The ring of fibrous tissue above and the triangular fibro-cartilage below limit the movements. The apex of the cone alters its position owing to the head not being circular and the movement of flexion which the head experiences. The ulna in pronation is extended, abducted, and rotated. The radius is flexed and adducted as well as rotated; so far as the ulna is concerned, this act is aided by the movements of the ulna. The action is easier and a strain less necessary than if the ulna were fixed. The movements of the radius on the humerus are flexion or extension, a shifting inwards or outwards and rotation of the head. The ulna moves backwards or forwards on the trochlear surface, and rolls in or out; extension of the ulna is attended with motion of the lower end out. It may here be mentioned that the methods by which ellipsoidal, hyperboloidal, spherical, or paraboloidal curves are produced physically, suggest to one that similar conditions may prevail in the construction of similarly curved joints.

Rotation of the forearm is rarely a simple action. It is commonly associated with movements of flexion and extension of the elbow-joint. To this the character of the muscles in the forearm bears witness. There are apparently varying degrees of inter-association of these actions in animals. Leaving out the intrinsic muscles, one may easily gather from a study of the pronator teres how the association arises. This muscle draws the forearm towards the arm and at the same time turns the radius over the ulna. If two half-discs of cardboard be taken and so placed that the circumference of one will represent the course of the upper part of the humeral attachment of the teres as the humerus moves towards the forearm, whilst the other disc is so placed that its circumference will represent the course of the attached end of the teres in movements of the radius inwards, then, by attaching threads to each disc to represent the muscle band at each stage of movement a surface may be constructed. This surface is of a complex nature and illustrates the direction of the muscle band at any particular part of the excursion.<sup>4</sup> It may be urged that the articular surfaces show variations. Professor Lesshaft's classification is an attempt to deal with a subject which the addition of numerous facts has rendered difficult. Although complex for the student who wishes to have his attention riveted upon the shape, ligaments, lines of pressure, and connexions of joints, it will be regarded as a thankworthy attempt to deal with a great difficulty. It

is now proved that the articular surfaces, formerly regarded as very simple, are more complex, but are still within the scope of the mathematician who deals only with the simpler relations. The more difficult surfaces and forms are appropriately referred to the artist who may give us a key to the complex conditions which nature presents.

Queen's College, Galway.

## ON A NEW METHOD OF PRESERVING MUSEUM SPECIMENS.

BY HUGH GALT, M.B., F.F.P.S. GLASC., D.P.H. CAMB.,  
PATHOLOGIST TO THE GLASGOW SAMARITAN HOSPITAL FOR WOMEN;  
PROFESSOR OF FORENSIC MEDICINE AND PUBLIC HEALTH,  
ST. MUNGO'S COLLEGE, GLASGOW, ETC.

It will be admitted by all who have had any considerable experience in the matter that the methods at present in use for preserving gross pathological specimens in such a way as to enable the latter to be employed as illustrations are very far from perfect in many respects, and that finality has been reached in this direction few will venture to assert. Until quite recent years the almost universal method of preservation was by keeping the specimens in a large relative bulk of spirit of wine, after preliminary washing with water and soaking in several changes of spirit of wine. This method, while satisfactory enough with regard to the prevention of decomposition and the retention of the structural relationship of the parts, had three serious defects. Firstly, it was costly, particularly where a large number of specimens had to be dealt with; moreover, the alcohol evaporated unless the jars were almost hermetically sealed and had to be replenished or even entirely renewed at intervals. Secondly, the final result of the alcohol was to cause considerable shrinkage of the specimen and thus greatly to destroy its illustrative value. This result, of course, is particularly evident in the case of succulent tissues or organs such as the liver, spleen, &c. Thirdly, the colour of the specimen in the fresh state, except in the case of pigment insoluble in alcohol or carbonaceous matter, was soon completely, or almost completely, lost, the tissues taking on a uniform yellowish white colour, so that, for example, a cancerous nodule in the kidney could not be distinguished by its colour from the surrounding renal tissue. This is, perhaps, the most serious objection. There is no scientific objection on the ground of cost, and as to the shrinkage of the specimen accurate original measurement will to some extent minimise this disadvantage; but no minute description of the original colours (in the absence of colour-photography or the costly and often unfaithful painting in colours) can overcome the last defect.

On the properties of formaldehyde as a preservative of decomposable organic tissues partly depends a more recent method of preserving museum specimens, although the final preservative fluid chiefly employed in conjunction with formaldehyde is essentially diluted glycerine. For some time it was thought that in a solution of formaldehyde in water, containing about 40 per cent. of the gas and commercially known as formalin, we had a liquid which would be free from the disadvantages attaching to alcohol as a preservative. As it prevents decomposition even when very largely diluted with water the first objection to alcohol is surmounted, for the cost of a solution of formalin sufficiently strong to prevent the decomposition of animal tissues is comparatively trifling. With regard to the second objection, however, there is little if any gain, as even in a very dilute solution formalin not only causes shrinking of the tissues, but hardens them and renders them brittle. On the third objection there is again little real gain, for while formalin does not bleach the natural colours like alcohol, it gradually approximates the various shades until the specimen becomes ultimately of a slate colour. All the foregoing applies equally to formaldehyde vapour. In addition, formalin has inherent objections. Its vapour is irritating to the air-passages; it acts deleteriously on the hands; being volatile it slowly evaporates; while it is occasionally unstable even in diluted solution.

Perhaps the best-known modification in the employment of formalin in the preservation of specimens is Kaiserling's. Here the tissue is really only fixed in a solution of formaldehyde with acetate and nitrate of potassium; after treatment with 80 per cent. and 95 per cent. alcohol the

<sup>3</sup> Chomitzky, quoted by Lesshaft.

<sup>4</sup> Report of the meeting of the British Association at Southport.

specimen is finally preserved in a 20 per cent. aqueous dilution of glycerine with 10 per cent. acetate of potassium added. While I am informed that in some hands this method has given very fair results, personally I have to express my dissatisfaction with it. Acting strictly according to the instructions given the final results were very uneven, and in no single case could I get a specimen to retain for a length of time anything like its appearance in the fresh state, while the necessity of keeping the specimens thus treated carefully covered from the light must always remain a very real objection. It is evident, for instance, that specimens preserved by Kaiserling's method may require to be frequently uncovered and exposed to the light when being utilised for demonstration, so that in a longer or shorter time the natural colours entirely disappear. A museum of specimens preserved by Kaiserling's method would be on the same level as a picture gallery with the pictures facing the wall. Moreover, there are certain specimens (uterine fibroids and dermoid cysts for example) in which the colour of the specimen in the fresh state is so nearly and uniformly white that no advantage attaches to Kaiserling's or any other method requiring special treatment for the retention of colour. On the other hand, it is certainly advisable that as far as possible museum specimens should be prepared and preserved by a single method.

The foregoing facts led me some three years ago to institute a series of experiments with various substances with the view of finding whether a satisfactory method of preserving museum specimens could not be devised which would be free from the objections applicable on the one hand to alcohol and on the other to formaldehyde and its modifications. It will be at once apparent that I had a fairly large field to draw upon. A number of possible agents were neglected on account of initial cost, instability, poisonous properties, or for some other reason; but, as the following list will show, I had still ample ground in which to search for a substitute or substitutes, partial or complete, for alcohol and formaldehyde. I made in all between 70 and 80 experiments with the following agents, singly or in combination: alcohol, chloroform, formalin, glycerine, arsenic, carbolic acid, sodium chloride, potassium acetate, potassium nitrate, and chloral hydrate.

Without going into the details of the separate groups of experiments I may say that the first positive result was found in an aqueous solution containing 15 per cent. of glycerine and 0.1 per cent. of arsenic. This solution, after the usual preliminary treatment of the specimen by washing with water and fixing in 80 per cent. alcohol for from one to four days is cheaper than alcohol; it shrinks the tissue very slightly and the natural colours are fairly well retained, though somewhat dulled. The main objections are that the method is still somewhat costly (roughly the fluid costs 1s. 6d. per gallon) and that a greyish sediment is for many months gradually deposited on the glass of the jar and on the specimen itself. Not for some little time did it occur to me that possibly a watery solution of certain salts might suffice. Once the idea did present itself I assiduously experimented with the four compounds at the end of the foregoing list. It was early evident that so far as the mere preservation of a specimen was concerned a very simple saline solution was all that was necessary; but in order to avoid shrinkage and persistent oozing of tissue fluids with consequent discolouration of the menstruum, and to conserve as far as possible the natural colours, certain combinations and preliminary treatment were necessary. This, then, was the crux of the whole question, and only after numerous experiments and long waiting was I able to assure myself that the method which I finally fixed upon was as free from objection as possible. Before describing the actual method I may say that in my opinion it is almost certainly impossible to preserve specimens for an unlimited time in such a way as to retain their natural colours in the fresh state, and that at most we can only hope to retain the natural colouring to such an extent as will show differences of colour corresponding in kind to the differences evident in the fresh specimen.

Apart from preliminary treatment, the liquid which I have employed during the last two years for preserving museum specimens at the Glasgow Samaritan Hospital for Women is composed as follows: common salt, five ounces; potassium nitrate, one ounce; chloral hydrate, one ounce; water, 100 ounces. The above solution answers all the objections previously stated. 1. The cost is about 4d. per gallon, as compared with 2s. 6d. for 80 per cent. alcohol (methylated spirit) and 1s. 6d. for the final preservative

liquid in Kaiserling's method. The cost of the preliminary treatment is the same as in the old method and much less than in Kaiserling's, as 95 per cent. alcohol is not required. 2. The shrinkage of specimens is distinctly less than in Kaiserling's method, and much less than in the old method. What little shrinkage is present is due to the necessary preliminary treatment. 3. Retention of colour is after all the chief point, and, as my specimens show, this has been retained in a very high degree and without the troublesome after-treatment which is necessary in Kaiserling's method.

The preliminary treatment is the same as in the old method. As the preservative liquid has little or no coagulant powers the specimen if put into it without preliminary treatment would remain too soft and by tension and compression distort the original relations and measurements. After trimming, if necessary, and washing in running water for several hours, the specimens are put into a large excess of methylated spirit for from six hours to as many days, according to the size and nature of the specimen, changing the spirit once or twice should there be much oozing of tissue fluids. In the case of large or soft specimens the addition of 0.5 per cent. of formalin accelerates the "setting" of the tissues. From this the specimen is transferred direct to the preservative liquid, in which it occasionally floats for a short time until it is sufficiently permeated. In some cases, after a few weeks it may be necessary to renew the liquid; beyond this it is only necessary to replenish the jar with water to make up for that gradually lost by evaporation. Loss of water may of course be prevented by sealing the cover of the jar, but this interferes with the abstraction of the specimen for detailed examination, and as the cost of the water is *nil* there is no advantage in sealing the jar.

It only remains to enumerate the advantages of this method over any of the older ones. 1. The item of cost is important. So long as the results are even only equal to those of the other methods the cost should decide the adoption of one method in preference to another. Further, this method enables men in private practice to preserve many interesting specimens at a small cost, which would otherwise be lost. Even in hospitals it is clear that, *otheris paribus*, the cheapest method should be employed. 2. It is at least as simple to begin with as the old method, and requires less after-attention; it is simpler at all stages than Kaiserling's method. 3. As regards the action of light, specimens thus preserved do not require to be kept in the dark; they are unaffected even by strong sunlight. 4. The preservation of colour is more nearly complete than in the older methods. 5. It has the advantage of portability. The solid ingredients can be carried any distance, and the liquid prepared as required. 6. As it is non-volatile in character jars require to be replenished with water only if the solution remains clear. 7. Its non-poisonous and non-irritating properties. 8. Its action on the cellular elements of the tissues is negative, enabling microscopical sections to be made after long intervals. In the older methods microscopical sections made after the lapse of more than a year or two stain diffusely. 9. Shrinking of the specimen is very slight, as indicated by actual measurements.

Little need be said with regard to the several ingredients of the liquid except in a general manner. It is well known that common salt itself only acts as a permanent preservative in the form of strong brine. The addition of a small proportion of chloral hydrate greatly reduces the proportion of common salt necessary and adds to the efficiency of the liquid as a preservative. As far as the retention of colour is concerned the potassium nitrate is indispensable. In an emergency a specimen may be put temporarily into the preservative liquid direct, but the result in this case is that the specimen tends to become uniformly stained or coloured by diffusion, while the liquid part of the fat (if there is any present) collects on the surface. Rarely, also, a fungoid growth may form on the surface, necessitating renewal of the liquid. The specimen must at some time be subjected to the "preliminary treatment" if the proportions observed in the fresh state are to be retained.

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### RETENTION OF URINE FROM THE PRESENCE OF A BOTTLE IN THE RECTUM.

By JOHN GOOD, M.R.C.S. ENG., L.S.A.

ONE evening in January, 1895, a soldier brought me a message to visit his father, aged 74 years, a club patient living three miles distant in the country, as he was "in great pain and could not pass water." I rode out and catheterised, finding no obstruction or difficulty in passing a No. 10 gum-elastic catheter. The old man was in bed. I advised hot applications and told him to send me word next morning if he was unable to micturate. Next morning the soldier reappeared; his father was again in agony and again was as readily relieved. The preceding evening I had been informed that his bowels were acting well; this morning I learned that he had diarrhoea and that the stools were bloody, so I made a rectal examination and felt a firm, hard, smooth, round body that I could not recognise or learn anything about from the patient. The idea of its being a foreign body did not then occur to me. Accordingly I wrote to my partners in the adjacent town, stating my difficulty and asking for a consultation next day. The following morning I again catheterised and worried my patient into confessing that he had put a bottle there to "plug the opening" as his diarrhoea had troubled him so much, and "it had slipped in." My fingers were not long enough to grasp the convexity of the bottle, nor could I drag it forward from off the coccyx, where it was tightly lodged with its neck tilted upwards and forwards towards the base of the bladder, but by looping the gum-elastic catheter I had just used I was able to raise the bottle sufficiently off the coccyx to pass the loop beneath it and up around the body of the bottle, then with a hard pull I dragged it forward and it simply "shot out" of the bowel. The bottle contained only a little bloody mucus, and was long-necked and cylindrical, as used for Worcester sauce, but I regret that I did not take its dimensions. On its removal all urinary and bowel troubles ceased. This case is, I believe, unique in retention of urine being produced mechanically through the casual presence of a foreign body in the rectum.

Stockport.

#### CURIOUS SYMPTOMS AFTER EXTRACTION OF A TOOTH.

By W. COLLIER PRIDHAM, L.D.S. ENG.

I HAVE just seen an article by Dr. A. Stanley Green which appeared in THE LANCET of August 10th, p. 372, and I should like to be allowed to report a similar case, which, however, differed from Dr. Green's in that the patient under my care had taken no anæsthetic, though showing the same symptoms as those described.

My patient was a man, aged 30 years, who applied at the Royal Dental Hospital of London to have a fractured tooth removed. The fracture had been done a week previously, and in the interval the man had suffered extreme pain. The roots of the first lower molar on the left side were removed without difficulty, the patient, however, immediately subsequently to the operation complaining of great pain. This was almost immediately relieved by the application of hot water to the gums, and at this point the patient appeared to be quite well. Within five minutes of the extraction he complained of severe "pins and needles" in the legs and arms, became rigid and quite cold, with a bad colour, hurried respirations, dilated pupils, strong contraction of the muscles of the arm and forearm, flexure of the fingers, and considerable adduction of the thumbs. The teeth were clenched, but the patient was able to answer questions with some difficulty, and he remained conscious during the whole attack which lasted for about half an hour. The hands and arms were

well chafed and doses of sal volatile were administered. As in Dr. Green's case, the patient was eager to be allowed to sit up, at least partially. The symptoms yielded to continued efforts to restore warmth, and the man recovered slowly till he was able to warm himself by swinging his arms about. He eventually left the hospital apparently little the worse for the attack.

#### ST. GEORGE'S HOSPITAL.

A CASE OF DOUBLE OVARIAN CYST COMPLICATED BY  
SUPPURATIVE CALCULOUS CHOLECYSTITIS.

(Under the care of Mr. H. W. ALLINGHAM.)

THE co-existence of gall-stones with some other abdominal lesion is by no means rare, and the explanation given below by Mr. Keyser is probably true—namely, that the flow of bile is interfered with, thus predisposing to the formation of calculi. A further cause may be found in the fact that an abdominal tumour of any great size will tend to cause constipation, and thus favour intestinal decomposition, with the result that micro-organisms are more likely to make their way up the bile-ducts. For the notes of the case we are indebted to Mr. Charles R. Keyser, surgical registrar.

A woman, aged 64 years, was admitted into St. George's Hospital on Sept. 9th, 1901, under the care of Mr. H. W. Allingham, with a history that for three months she had noticed pain and swelling in the right side of the abdomen which had lately increased in size. The pain was gradually becoming worse; a fortnight before she had an attack of diarrhoea and sickness which, however, only lasted for a day. Since then there had been no vomiting and the bowels had acted daily. On admission she looked thin and ill and her temperature was 100° F. The tongue was coated. Examination of the abdomen showed that the right lower half was distended and occupied by a soft fluctuating tumour, the upper border of which almost touched the level of the umbilicus and was well defined, whereas the lower edge could not be felt. There was some tenderness over the right side of the tumour and a thrill could easily be obtained on palpation. It was noticed that in the lowest part of the cyst on the right side there was a small, rounded, hard mass to be felt. Per vaginam a large soft mass could be felt on both sides of the pelvis which was continuous with the abdominal tumour; fluctuation was easily obtained from one side of the pelvis to the other and also from the tumour as felt per abdomen to the mass in the pelvis.

On Sept. 16th, an anæsthetic having been given, Mr. Allingham opened the abdomen in the middle line below the umbilicus and found a large multilocular, left ovarian cyst which projected over on to the right side. Owing to the size of the cyst it was tapped *in situ* and a good deal of clear, straw-coloured fluid was evacuated. The cyst was then brought to the surface, the pedicle ligatured with strong silk by means of the Staffordshire knot, and the tumour removed. It was then found that there was a right ovarian cyst of the size of a clenched fist, and this was removed in a similar manner. There were very few adhesions present. Before closing the wound a tumour was felt close under the liver and an incision was made over the mass just to the right of the middle line after suturing the lower wound. The swelling was due to a distended gall-bladder which was opened and about two ounces of pus were evacuated. Three faceted gall-stones were also seen and removed. The gall-bladder was sutured to the skin at the lower part of the wound, the upper part being closed, and iodoform gauze lightly packed into the gall-bladder. The patient was a good deal collapsed after the operation, but

soon rallied when strychnine and brandy had been injected subcutaneously and an enema of normal saline solution had been given. The temperature, which for the first three days had been slightly raised at night, became normal and except for temporary retention of urine, which necessitated the use of a catheter, the patient made an uneventful recovery, and left the hospital on Oct. 12th, both wounds being practically healed.

*Remarks by Mr. KEYSER.*—The chief interest in this case lies in the fact that in spite of her age and in the severity of the operation the patient made an uneventful recovery; also that the pathological condition which in all probability made her seek medical advice was not the enlargement of the ovarian cysts but the suppurative cholecystitis, the existence of which was not even thought of either by the patient or the surgeon until the abdomen was actually opened. The pain and temperature had been considered due probably to a twisted pedicle of the ovarian cyst. As this was not the case some other cause of the symptoms was immediately sought for. This shows, therefore, that a surgeon ought not to be content with treating any obvious disease only, but also to make sure, as far as possible, that there is no other lesion which might account for the symptoms. Personally I have no doubt that the temperature and the pain were in this case caused by the trouble in the gall-bladder and not by the ovarian cysts. The manner in which gall-stones are formed and suppuration takes place is also of interest. Probably the sequence of events is as follows. The presence of the ovarian cysts (in this case), by preventing free peristalsis of the intestines, caused a stagnation of bile in the gall-bladder: this diminished the power of resistance of the walls of the gall-bladder by lowering its vitality and allowed the entrance of the bacillus coli communis; this latter, together with the partial stagnation of the bile, was then followed by precipitation of cholesterin and the formation of the calculi. The original cause of the trouble—i.e., the pressure of the ovarian cysts—still continuing, and probably increasing, allowed the micro-organisms to enter the gall-bladder in larger numbers, and suppuration was the result. There has always been some difficulty in deciding why in some cases micro-organisms cause the formation of gall-stones and in others acute suppurative cholecystitis, and the reason has been ascribed by some to virulence of the bacteria; a mild attack being followed by the formation of calculi, whereas suppurative cholecystitis is the result of a large dose of the virus. This theory seems to be borne out by the case related above. I am much indebted to Mr. Allingham for permission to publish this case.

## Medical Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

#### *Ulceration of the Œsophagus and Stomach due to Swallowing Strong Hydrochloric Acid: Lessons of Treatment Deduced from Three Cases.*

A MEETING of this society was held on Nov. 12th, Mr. WARRINGTON HAWARD, the Treasurer, in the absence of the President, being in the chair.

Mr. C. B. KEETLEY read a paper upon Ulceration of the Œsophagus and Stomach due to Swallowing Strong Hydrochloric Acid: Lessons of Treatment Deduced from Three Cases, which is published in full at p. 1328 of the present issue of THE LANCET.

Mr. E. P. PATON mentioned the case of a woman who had been under his care suffering from the effects of acid poisoning. He at first treated the case by the passage of a tube and washing out the stomach, and the patient for the first few days improved considerably. The stomach, however, became distended and very tense, but not dilated, and it could be felt in the abdomen as a hard ball of about the size of a foetal head. This distension was attributed to obstruction both at the pylorus and at the cardiac end of the Œsophagus. The abdomen was opened, an incision was made into the stomach, and a finger was passed through the pylorus into the duodenum. The duodenum was, however, so ulcerated that it gave way and a pyloroplastic operation had to be performed; the

patient, however, died a few days later. At the necropsy it was found that there was only one small portion of healthy mucous membrane lining the stomach. Mr. Paton regretted that he had not performed a gastro-enterostomy, as he thought that that would have given the patient the best chance.

Mr. CLINTON DENT was of the opinion that in a large proportion of the cases the injury was at the pyloric end of the stomach. He said that pyloroplasty was to be preferred to Loreta's operation as it was possible in that way to obtain a good view of the mucous membrane of the stomach and duodenum and to estimate the extent of the mischief. He did not consider that a Murphy's button was a satisfactory arrangement and he advocated either Senn's plates or stitching. He thought it best to feed the patient as soon after the operation as possible and said that the food should be given hot.

Mr. HAWARD said that the Œsophagus was seldom constricted by the effects of poison, and that often when swallowing was difficult a fair-sized bougie could be passed into the stomach, showing that the constriction was of a spasmodic nature. He was in favour of the plastic operation on the pylorus, and then if there was any difficulty, such, for instance, as the ulceration of the duodenum, a gastro-enterostomy could be performed. He preferred to use Senn's plates rather than Murphy's button, and he did not think that any contraction was likely to occur around the gastro-enterostomy opening when it was sewn up with a continuous suture. He was of the opinion that it was extremely important to feed the patients as soon after the operation as possible. He had never had cause to regret feeding a patient too soon after operation, but he had had cause to regret not having done so earlier in certain cases.

Mr. KEETLEY, in reply, said that the case which Mr. Paton had related was only another example of the necessity for early operation. He thought that Loreta's operation was to be preferred and was certainly safer than pyloroplasty or gastro-enterostomy. He was in favour of using a Murphy's button, as that seemed to prevent the "vicious circle"—i.e., the passage of the contents of the stomach into the duodenum and then through the gastro-enterostomy wound into the stomach again. Even if the Murphy's button fell back into the cavity it could easily be removed through the stomach, and the operation was attended by very little risk.

### MEDICAL SOCIETY OF LONDON.

#### *Exhibition of Cases.*

A MEETING of this society was held on Nov. 11th, Dr. W. H. ALLCHIN, the President, being in the chair.

Mr. T. H. KELLOCK showed a case of Symmetrical Disease of the Ankle-joints in a child, aged three years and four months. There was a history of tuberculosis on the mother's side and the father had had rheumatism in both knees two months ago. There was no history of gout or syphilis. There was one other healthy child. The swelling of the ankles was first noticed a year previously, the one ankle being affected a little while before the other. Four months ago the skin became ulcerated over both ankles. When the patient was admitted to the hospital the ankle-joints were enlarged and pulpy, without pain or tenderness. There were several superficial ulcers round both, discharging a little pus; these had almost entirely healed under simple treatment. There was a fusiform swelling on the back of the carpus of the left hand. This, too, was neither painful nor tender. There was no enlargement of glands with the exception of some in the left groin, probably caused by a small abrasion in the knee. The spleen could just be felt. No signs of tubercle were present in the lungs or other viscera. The temperature was normal and the child's general health appeared to be good. The case was probably one of osteo-arthritis.—Mr. J. HUTCHINSON, jun., suggested that the case was a tuberculous affection of the joints and said that he had seen several cases in children with multiple tuberculous affection of the joints which recovered completely.—Mr. KELLOCK replied that had the ulceration been tuberculous it would hardly have healed up so rapidly under the most simple treatment.

Mr. M. S. MONIER-WILLIAMS showed a case of Ulcerative Colitis with Paralysis of the Eleventh and Twelfth Cranial Nerves in a man, aged 56 years, who had enjoyed good health until May, 1897, when diarrhoea and hæmorrhage commenced from no apparent cause. The motions were

excessively offensive, semi-fluid in character, and containing, besides blood and mucus, occasionally a very little pus. There was no pain except a gripping pain when passing motions, which varied in number from five to 15 in 24 hours. There was no rise of temperature nor was there vomiting. The examination of the abdomen and the rectum revealed nothing abnormal. A course of mercury and iodide of potassium had little or no effect. Rectal irrigations with a solution of nitrate of silver (10 grains to the pint) and of a saturated solution of boric acid held the complaint in check for a time and a course of sulphur waters at Llandrindod Wells and also at Harrogate benefited the patient for a little, but on the whole he got steadily worse until December, 1900, when he was excessively ill. He had from 10 to 20 hæmorrhagic stools daily. There were extreme emaciation and loss of control of the sphincter ani. Dr. Hale White in consultation agreed that right-sided colotomy offered the best chance of saving the patient's life, and Mr. George Turner did the inguinal operation. As soon as the wound was healed and the artificial anus was ultimately fitted with the plug, now exhibited, he rapidly improved. He recovered control over the sphincter ani and was able to follow his ordinary life without inconvenience. On Jan. 4th, 1899, the same patient suddenly became quite hoarse in his voice, felt a little sick, but not otherwise ill, and noticed that his tongue on protrusion went to the right side. On examination the right vocal cord was found to be paralysed, the tongue was deflected to the right side, and the right side of the palate was partially paralysed. It was considered probable that there was a vascular lesion, probably thrombotic, affecting the nuclei of the hypoglossal and spinal accessory nerves on the right side. The patient had an apical systolic cardiac murmur. Subsequently the upper part of the right trapezius muscle showed signs of wasting and there was now complete wasting of the right side of the tongue. The patient recovered his voice, but the right vocal cord remained much as before, the left coming over to meet it.—Mr. GEORGE TURNER said that the colotomy had been performed in order to allow of more efficient local treatment being carried out. He suggested that the symptoms might have been due to thrombosis of the mesenteric vessels and a somewhat similar case had been published by Sir W. Gull.—The PRESIDENT suggested that considering that the patient had an affection of the mitral valve it seemed more probable that the paralysis of the cranial nerves was due to an embolus rather than to thrombosis.—Dr. R. L. BOWLES pointed out the relation which these cases bore to the nervous system and quoted a case in which after several months recovery took place.—Mr. L. A. BIDWELL suggested that an anastomosis between the ileum and the sigmoid would be the right means to treat these cases of ulcerative colitis, as that would place the affected part out of circuit.—Dr. HALE WHITE thought that the short-circuiting of the gut would be the most satisfactory treatment if one could be certain that there was no ulceration of the sigmoid or rectum.

Mr. W. H. BATTLE showed a Boy who Broke his Left Thigh in April of this year. The thigh was put up in plaster-of-Paris; this was removed at the end of three weeks on account of excessive swelling of the thigh, which was said to have been three times the size of the other one. Since that time the femur had united and now the patient was able to walk about. The swelling was said to be diminishing in size. The left femur was changed into a fusiform bony swelling measuring 15 inches, twice the size of the left. There was no pain and the child appeared to be in good health and got about. There was no softening and no enlarged glands could be felt.—Mr. GEORGE TURNER suggested that the case was one of exaggerated callus and mentioned a similar case in an adult in which it eventually entirely cleared up.—Mr. BATTLE, in reply, said that he thought the diagnosis lay between sarcoma, excessive callus, and excessive extravasation of blood owing to a scurvy condition. He had never seen such excessive callus in a child but had in an adult suffering from locomotor ataxia.

Mr. H. L. BARNARD showed two cases of Snap-thumb, one in an adult on whom he had operated, the patient being perfectly cured, and the other in an infant, one and a half years old.

Mr. A. PEARCE GOULD showed a case of Actinomycosis of the Breast in a girl, aged 19 years. She had enjoyed good health until the end of August, 1901, when she complained of pain of a stabbing character in the left mammary region. Five weeks later she noticed that the left breast was more

prominent than the right. This increased until her admission into the Middlesex Hospital on Oct. 29th. The breast was then considerably and uniformly enlarged, fluctuating throughout, but neither painful nor tender. The skin over it was not discoloured. An incision was made and several ounces of green, slimy, offensive pus escaped. There was imperfect resonance and other evidence of thickening of the pleura. In the pus the mycelium of actinomycosis was found. All the hitherto recorded cases of actinomycosis of the chest-wall, including the mamma, had been secondary to disease of the lungs, pleura, and liver, and this was no exception to that rule. But the case was interesting because of the very slight evidence of the pulmonary disease and the rather unusual character of the abscess.—Dr. A. F. VOELCKER suggested that the primary disease was in the pleura and that the breast was secondarily involved. He mentioned the case of a boy who had died from this disease in whom numerous nodules of recent actinomycosis had been found in the skin and old foci in the pleura and liver.—Dr. E. MARKHAM SKERRITT (Bristol) mentioned a case in which there was evidence of actinomycosis of the lung, later there was evidence of involvement of the liver from which the patient died, and at the necropsy the only evidence of involvement of the lung was a track of scar tissue.—Mr. PEARCE GOULD said that there was probably more than one form of streptothrix giving rise to the condition known as actinomycosis.

Mr. A. CARLESS showed a case of Amputation of the Whole Upper Extremity for Chondro-sarcoma in a woman, aged 54 years. For three or four years previously she had complained of pain in the muscles of the right shoulder and had been treated for muscular rheumatism. Ten months previously she had noticed a hard swelling below the right clavicle; the pain increased and became shooting in character, extending down to the finger and keeping her awake at night. Two months before she was seen by Dr. Soltan Fenwick at the London Temperance Hospital and an operation was advised. When first seen at King's College Hospital a swelling only existed below the right clavicle in the region of the coracoid process. An x-ray examination gave no definite result. When admitted the sub-clavicular swelling was large and another softer one had developed below the outer portion of the scapular spine. An indefinite mass could be detected in the right axilla, and on inspection the whole contour of the shoulder was altered, suggesting a growth of the scapula, enveloping the head of the humerus which could be felt to be normal in size and position. The movements of the shoulder were limited, especially abduction and rotation, and some crepitus was noticeable in the joint. The muscles of the right arm were atrophied. There was no œdema of the arm and the radial pulses were equal on the two sides. No glands could be felt either in the axilla or in the supra-clavicular fossa. The whole extremity was removed by Berger's method. The patient left the hospital after three weeks with the wound completely healed. The growth proved to be a chondro-sarcoma.

Mr. J. LYNN THOMAS showed the photograph of a case of Occipital Meningocele. The patient was a child, aged four months, who had had a tumour at the back of the head since birth which had been getting gradually larger; it was attached to the skull by a pedicle over the posterior fontanelle and was of the shape of a very large fetal head. It was translucent and fluctuating and had been tapped several times, and it had a number of large veins visible upon its surface when the skin was thin. The child had never been able to move its head on account of the enormous size of the meningocele. Operation was performed on Sept. 24th, 1901. Skin flaps were dissected off the meningocele, leaving the numerous veins untouched. A pair of strong occlusion forceps, six inches long, were then applied to the pedicle and gradually closed, whilst the meningocele was tapped. The pedicle was rendered water-tight by means of a Gely's suture and two rows of continuous sutures. The skin flaps were brought together and collodium dressings were applied. The recovery was uneventful.

Mr. W. H. BATTLE showed a case of Closure of Artificial Anus after Operation for Chronic Obstruction. The patient was a man, aged 49 years. He had been in good health until Jan. 1st, 1899, when he felt pain in the lower part of the abdomen, with constipation. About 14 days later he had offensive vomiting and diarrhoea, mucus was passed by the bowel, and he lost flesh. An exploratory incision was made in the median line below the umbilicus. The large

intestine was found to be thickened and distended. The upper part of the sigmoid flexure was fixed to the pelvic brim. Below this point a lump could be felt, thought to be malignant growth. There was some adhesion of the small intestine to the swelling. The incision was closed and a left inguinal colotomy was performed. A month later he was discharged, wearing a colotomy belt. On June 3rd, 1899, he had some return of the symptoms and the abdomen was reopened in the median line. The growth was found to be smaller than at the previous operation, but still fixed to the pelvic brim. On April 17th, 1901, he was readmitted. Up to Christmas, 1899, he discharged faeces only by the colotomy opening, but about then he began to pass faeces per rectum. The first time he had severe pain in so doing, the pain lasting two hours. Since then faeces had passed both ways. He had greatly improved in health. The abdomen was opened in the median line through the old scar, but no growth or intestinal obstruction was found. On May 30th the colotomy opening was closed and the patient was discharged on the fortieth day with the wounds almost healed.

### CLINICAL SOCIETY OF LONDON.

#### *The Operative Treatment of Cancer of the Pyloric Portion of the Stomach.*

A MEETING of this society was held on Nov. 8th, Mr. HOWARD MARSH, the President, being in the chair.

Mr. B. G. A. MOYNIHAN read a paper on the Operative Treatment of Cancer of the Pyloric Portion of the Stomach. He said that an examination into the records of cases of recurrence of malignant disease of the stomach after operation showed that the return of the growth was almost always local, in the stomach wall at or near the line of section, or in the glands or lymphatic vessels which drained the affected area. It had been estimated by Hemmeter that recurrence occurred in 99 per cent. of cases submitted to operation. In order to perform an operation which should prevent recurrence they must base such operation upon a knowledge (a) of the mode of invasion of the stomach by the primary growth, and (b) of the lymphatic distribution in the stomach and of the position of the glands into which the vessels drained. The researches of Borrmann and Cuneo had shown that the most common point of origin of carcinoma in the stomach was 2.4 centimetres from the pylorus, on or near the lesser curvature. From that point the disease spread gradually, but more rapidly and to a greater extent towards the body of the stomach than towards the duodenum. On the stomach side the growth was not equal in all directions; there was a pronounced tendency for the induration to spread towards the curvatures. Towards the duodenum the spreading was slower and invariably less extensive. If sections were made at the edge of a malignant neoplasm it would be found that the edge of induration corresponded to the limit of growth in the mucosa. In the submucosa the growth extended much further in a solid unbroken mass, and beyond the edge of this mass isolated nodular deposits of growth were present, which became smaller as the distance from the tumour increased. The subserous and serous coats were implicated approximately to the same extent as the mucosa. The lymphatic glands of the stomach were situated chiefly along the vessels. 1. The coronary group lay along the lesser curvature. These glands were continuous at the origin of the coronary artery with those along the upper border of the pancreas. 2. The hepatic group lay along the hepatic artery and some of its members along the pyloric artery. The glands of the greater curvature lay along the right gastro-epiploic artery. At the pylorus they were numerous and close together and passed behind the stomach to the head of the pancreas. The lymphatic vessels draining into these glands passed very obliquely in the walls of the stomach. Three chief lymphatic areas of the stomach might be described. An area along the lesser curvature, an area along the greater curvature, and an area comprising the greater tuberosity of the stomach extending up to the oesophagus and on the greater curvature as far as the limit of supply of the left gastro-epiploic artery (as far as the gastro-splenic omentum). In cases of malignant disease of the pyloric portion of the stomach the growth extended in the direction of the curvatures and the glands of the first two groups were affected, but the glands of the third group

and the area which they drained escaped. This latter area might be looked upon as an area apart, as one into which extension very rarely occurred, and as one, therefore, the lymphatic vessels and glands of which remained healthy. The term "isolated area" might well be employed to describe it. Upon the following facts an operation should be based: (1) malignant disease of the stomach most often commenced near the pylorus, just below the lesser curvature; (2) from its point of origin it spread most widely in the submucosa and chiefly towards the cardiac end of the stomach; (3) on the duodenal side it spread tardily and never extensively; (4) the drift of the growth was towards the curvatures; (5) the lymphatics draining the affected area passed to glands lying along the coronary and pyloric arteries above and the right gastro-epiploic and gastro-duodenal arteries below; and (6) the greater tuberosity of the stomach (the "isolated area") was very rarely involved. In order to ensure complete removal of the primary growth of the infiltrated lymphatic vessels and of the glands into which those vessels drained, it would be necessary to remove the stomach as far up on the lesser curvature as the point of abutment of the coronary artery, and on the greater curvature as far as the gastro-splenic omentum, and to remove the first portion of the duodenum. In order to make the operation simpler and quicker, a preliminary ligature of the coronary, the pyloric, the gastro-duodenal, and the left gastro-epiploic arteries was performed. After removal of this portion of the stomach, the anastomosis between the "isolated area" and the small intestine might be made by end-to-end approximation by Kocher's method or by suture of the cut ends and the performance of a separate gastro-enterostomy. The coronary artery was ligatured first, and it was to be found in the "ligament of Huschke," the falx coronaria, the folds of which inclosed it. The position of the artery could be defined by lifting up the liver and pulling the stomach downwards and outwards until a ridge was raised up in the peritoneum by the underlying vessel. The pyloric and gastro-duodenal arteries were best ligatured as they left the hepatic artery. The hepatic artery could be found just above the pylorus and could be made clearer by dragging the pylorus downwards and to the right.

Dr. P. H. PYE-SMITH said that Mr. Moynihan had called attention to the fact that that portion of the stomach which was situated below and to the left of the cardiac orifice was much less liable to be affected by carcinoma than was the pyloric end. This portion of the stomach was anatomically distinct from the rest of the stomach, being lined with epithelium of a different type from that which lined the rest of the stomach. He pointed out that the lesser curvature of the stomach was very much more frequently affected than the larger. The greatest difficulty in dealing with these cases surgically was the fact that an early diagnosis could seldom be made and long before any mass could be felt in the abdomen the disease had made such progress that it was impossible for the surgeon to remove the growth. He considered that in cases of pyloric obstruction with dilatation of the stomach it was better to short-circuit the intestine, which relieved the most acute symptoms due to the dilatation and allowed the patient to recover his general health before the more severe operation of pylorotomy was performed. He mentioned the case of a woman with an annular stricture of the colon in which colotomy was performed and the immediate symptoms were relieved: the patient was extremely collapsed after the operation, and he felt certain that had the severer operation of removing the annular stricture, which was very localised, been attempted at the time it would have been attended by a fatal result. The patient rapidly improved in her general health and a few weeks afterwards the stricture was removed, and five years later the patient was in good general health.

Dr. NORMAN MOORE said that it was most unusual for growth to spread from the pyloric end of the stomach into the duodenum. During nine years in which he had performed many necropsies he had never seen a single case in which the growth had extended from the stomach to the duodenum, although he had seen growths protrude through the pylorus into the duodenum but never involving the wall of the duodenum. He doubted whether the area of the stomach described by Mr. Moynihan as the "isolated area" was so rarely affected with new growth as he had made out. Out of 30 cases of carcinoma of the stomach in 11 the whole of the stomach wall was involved from the pylorus to the cardiac end, though he quite agreed that the cardiac end

was very much less liable to be affected than the pyloric end. He considered that when the stomach was involved by new growth it was generally in the form of one of the four following varieties: in the first variety the growth was confined to the pylorus and owing to the obstruction gave rise to enormous dilatation; in the second, which was commoner, the growth infiltrated the gastric wall to a greater or lesser extent along both curvatures, involving sometimes the whole stomach and even spreading to the œsophagus; in the third the growth involved the cardiac end of the stomach, and in this situation was always loose and very vascular so that hæmorrhage was liable to occur from it; and in the fourth the growth began in an old ulcer and this was commonly situated on the posterior wall of the stomach. Of secondary growths the most common situation was undoubtedly the liver; out of 30 cases it had been present in the organ in no less than 14. Next to the liver it was most usual to find the growth on the under surface of the diaphragm, and next in frequency in the lumbar glands. With regard to the duration of the disease he had known one case in which it had lasted for 60 months and in another it had lasted for 38 months. In most cases, however, the patients died within 18 months of the first symptoms. He thought that if the disease had lasted for seven months it was probable that secondary deposits would be found in other organs.

Mr. CHARTERS J. SYMONDS said that these cases were very disappointing so far as a cure was concerned; out of about 20 cases there was only one in which he felt justified in performing the operation of pylorotomy. In this case no tumour could be detected on examination. The growth was so limited that it seemed possible to remove it completely; when, however, further examination was made it was found impossible to remove the whole disease owing to the invasion of the posterior wall. He thought that a gastro-enterostomy would give as much relief as a pylorotomy, and it was not attended with the danger of the latter operation. He had seen cases which had extended over 12 months in which there were no secondary growths in the liver.

Mr. A. E. BARKER said the whole question turned upon the early diagnosis of the disease. He did not think, however, that the patients in whom the pylorus had been removed lived any longer than did those in whom a gastro-enterostomy had been performed. He referred to a case reported by Kocher in which the patient had lived nine years after the removal of the pylorus; he thought that such a favourable result might depend upon the nature of the growth and be similar to the case recorded by Dr. Norman Moore, in which the patient had lived 60 months. He referred to the great risk in exploring the abdomen in cases of carcinoma as compared to the risk in cases of non-malignant affections of the abdomen.

Dr. S. H. HABERSHON divided the cases into two classes—the first in which there were complete obstruction of the pylorus and dilatation of the stomach and the second in which the wall of the stomach was involved. These cases usually gave rise to symptoms of gastric irritation. No tumour could as a rule be detected in the abdomen in these cases. In one case which owing to the small size of the tumour seemed suitable for operation the patient died soon after its removal. The greatest difficulty in these cases was to distinguish gastric catarrh or simple ulceration from invasion of the stomach by new growths.

Mr. C. A. BALLANCE said that Mr. Moynihan had indicated the lines on which true advance in this branch of surgery would take place. He had always regarded carcinoma as a local infection and if the cases could only be diagnosed early enough there was hope of a permanent cure. He mentioned a case in which, owing to the growth not being felt, operation had been postponed for some months, and had the operation been performed when the patient was first seen the chance of a cure would have been far better.

Mr. G. H. MAKINS said that he should be interested to see the results of further cases operated on in the manner suggested by Mr. Moynihan. He mentioned the case of a young woman from whom he removed the pylorus as the growth seemed so limited. About seven months later the patient died from recurrent growths along the pancreas. He was of opinion that had he short-circuited the intestine the patient would have lived as long. He would certainly recommend short-circuiting rather than removal of the pylorus in most cases.

M. MOYNIHAN, in reply, pointed out that in 70 per cent. of the cases the growth was in a part of the stomach which

admitted of its removal. With respect to diagnosis he said that with a patient under medical treatment for gastric trouble at an age when one might expect to meet with cancer of the stomach, and when there was an absence of free hydrochloric acid in the stomach contents, then, whatever the physical signs and clinical condition might be, it was his practice to advise an exploratory incision. This had permitted him to obtain cases at an earlier date than elsewhere. Even in the early stage, however, the radical operation might not be permissible, because the disease might already have got beyond the limits of successful removal. He joined issue with Mr. Barker in respect of his view that life after gastro-enterostomy was at all comparable with life after partial gastrotomy or pylorotomy. Statistics showed at least one year's clear gain in favour of the latter. The improvement after gastro-enterostomy was great and immediate, but was quite ephemeral. He suggested that the attitude of surgeons towards these operations was their attitude of some years since towards operation for cancer of the breast. Gradually they had extended the limits of that operation, and no doubt as their knowledge increased they would do the same in regard to operations for cancer of the stomach. He believed that if attacked early by an operation on the lines he had described, they might hope in the future to obtain far better results than had been the case hitherto.

## OBSTETRICAL SOCIETY OF LONDON.

*Sloughing Fibroid of the Left Uterine Cornu showing Abnormal Relations.—Gonorrhœal Pelvic Peritonitis.—Tubal Mole.—Exhibition of Specimens.*

A MEETING of this society was held on Nov. 6th, Dr. PETER HORROCKS, the President, being in the chair.

Mr. ALBAN DORAN and Dr. CUTHBERT LOCKYER, communicated a paper on Sloughing Fibroid of the Left Uterine Cornu showing Abnormal Relations. The patient from whom the fibroid was removed, a single woman, aged 30 years, had been subject for a month to symptoms of pelvic inflammation with fever. There was an irregular moveable mass in the left fornix, rising into the left iliac fossa, and connected with a small anteflexed uterus. Mr. Doran performed supra-vaginal hysterectomy, removing the uterus and tumour with the left appendages; the right tube and ovary were spared. The patient recovered. The tumour, five inches in long diameter, was much larger than the uterus, projecting outwards rather than upwards from that organ. It was a true fibro-myoma in a necrotic condition, and adhered to the intestine and the omentum at its blunt-pointed outer extremity. This degenerative change apparently accounted for the febrile symptoms. At first sight the tumour simulated a fibroid in an undeveloped uterine cornu, but the Fallopian tube and ovarian ligament arose posteriorly, and not externally, and were attached to a deep groove between the uterus and the tumour. The left round ligament arose from the under surface of the tumour somewhat posteriorly, passing under it and forwards to the inguinal canal. A tumour with somewhat similar relations to a uterus much smaller than itself had recently been figured without any clinical history by Doederlein in Küstner's "Kurzes Lehrbuch der Gynäkologie" (Fig. 146). This outward growth of a fibroid of the cornu without outward displacement of the corresponding tube and ovary was very unusual. The sloughy state of the tumour demanded its removal, and the uterus could not possibly be separated from a growth of this kind, so that it was also removed.—After some remarks by the PRESIDENT, Dr. A. H. N. LEWERS said that among other points of interest the case described in the paper had an important bearing on the question of the mortality to be expected in cases of fibroid tumours of the uterus. Statistics had been published according to which the mortality from fibroids apart from operation appeared to be 0.000138 per cent., or about 3 in 2,000,000 cases. Now in such a case as Mr. Doran's, one of sloughing subperitoneal fibroid, which had already set up symptoms of pelvic inflammation with fever, it could not be doubted that apart from operation the case must have ended fatally. Leaving out of the question the other possible causes of death in cases of fibroids, was sloughing such a very rare thing? He had himself seen two cases comparatively recently. One had been already published. The other was one of the last cases in which he had removed the

appendages for uterine fibroid. In that case tying the vessels in the pedicles appeared to have in some way cut off the vascular supply of a fibroid near the fundus and caused it to slough. At all events, no evidence of sloughing (fever, fetid discharge, &c.) was present till after the operation. The patient died within a week, and at the post-mortem examination one of the fibroids near the fundus was found to have sloughed. Dr. Lewers called attention to the frequency with which mucoid degeneration was met with in fibroids, and he would be glad to know Mr. Doran's views as to the relation, if any, between mucoid degeneration and sloughing.—After Dr. G. F. BLACKER had joined in the discussion Dr. CUTHBERT LOCKYER drew attention to the fact that the term "suppurating fibroid" hardly conveyed the correct idea of the condition of the tumour at the time of removal, inasmuch as suppuration implied the presence of pus and of pyogenic organisms, and such were not present in the tumour. In reply to a question by Dr. Blacker as to the causation of the febrile condition of the patient Dr. Lockyer thought that it was possible for a pyrexia to result from the absorption of necrotic products in which no organisms could be found, and mentioned that this had been proved in the case of blood clot.—Mr. ALBAN DORAN, in reply, regretted that none of the Fellows of the society could offer any explanation of the abnormal relations. The tumour was certainly in the left cornu, and the displacement of the left round ligament was very unusual and seemed to indicate some malformation of the cornu. The term "sloughing" had been used for convenience in the title of this communication, though there was not the typical moist, fetid gangrene seen in Dr. Lewers's case, where the tumour was in close relation with the uterine cavity. In the present case the tumour and the cavity were far apart. The necrotic change probably came on because the shape of the tumour made its blood-supply liable to interruption. He believed that mucoid degeneration arose from similar causes assisted by feeble circulation. This seemed certainly the case in two instances of uterine fibroid in his own practice where menorrhagia was severe and the tumour caused pain, rare in fibroid disease. Mr. Doran removed the uterus without the ovaries with great benefit to the patients.

Mr. J. BLAND-SUTTON read a communication on a case of Gonorrhœal Pelvic Peritonitis.—Dr. DRUMMOND ROBINSON made some observations with regard to the case.

Dr. W. S. HANDLEY read a communication on a case of Tubal Mole with Encysted Hæmatocœle.—The case was discussed by Mr. DORAN, Dr. HERBERT SPENCER, Dr. W. S. A. GRIFFITH, Dr. LEWERS, Mr. BLAND-SUTTON, and Dr. LOCKYER.

The following specimens were shown:—

The PRESIDENT: Drawings of a case of Deciduoma Malignum.

Mr. DORAN: Fibroid of the Broad Ligament associated with an Ovarian Cyst.

Dr. LEWERS: Carcinomatous Uterus with Pyometra; the patient was well six years after the vaginal hysterectomy.

Dr. A. L. GALABIN: Papillomatous Cyst of (?) an Accessory Ovary.

Dr. T. W. EDEN: Cyclops Arrhynchus.

Dr. W. W. H. TATE: Fibro-myoma of the Uterus complicated with Double Salpingitis and Carcinoma of the Cervix removed by Vagino-Abdominal Hysterectomy.

The specimens were discussed by the PRESIDENT, Dr. GRIFFITH, Dr. LEWERS, Dr. LOCKYER, Dr. SPENCER, and Mr. J. H. TARGETT.

## OPHTHALMOLOGICAL SOCIETY.

*Mooren's Ulcer.—Keratitis in the Newly-born.—Exhibition of Cases and Specimens.*

AN ordinary meeting of this society was held on Nov. 8th, Dr. DAVID LITTLE, the President, being in the chair.

Mr. E. NETTLESHIP read a paper on Chronic Serpiginous Ulcer of the Cornea (Mooren's Ulcer). The terms "chronic serpiginous ulcer," or "Mooren's ulcer," were preferable to "ulcus rodens," which was another name for rodent epithelioma. The paper was based upon an examination of 71 cases, 12 of which were Mr. NettleSHIP's. Bowman was the first to describe a case in detail (1849), but Mooren rightly had the credit of discovering the disease as a clinically distinct species in 1867. The ordinary characters and course of the disease were described. Its usual duration was from four

to 12 months, and no cases were included that lasted less than two months, though certain cases running a less chronic course might perhaps be of the same nature. The subjects were adults from 23 to 71 years of age, rather less than a quarter were under 40 years of age, just half between 40 and 60 years, and rather more than a quarter over 60 years. A decided majority were males. In a large majority the attack in both sexes began in the winter half of the year, and degenerative changes, perhaps merely senile, lowered surface temperature, and perhaps some congenital defect of quality of the corneal tissue in certain persons were suggested as predisposing causes. The course of the disease strongly suggested infection, but no special micro-organism had as yet been found. In more than one-fourth of the cases both eyes suffered, sometimes with an interval of years, and the disease was often exactly symmetrical in the two eyes. The prognosis was always grave and was far worse when both eyes were attacked, only one in four of the double cases being arrested short of total leucoma; whilst of the single cases more than half recovered with some untouched cornea. The deeper parts of the eye remained healthy and vision was determined by the final state of the cornea and pupil. Treatment should begin with cutting away the overhanging and half-dead edge of the ulcer and applying an escharotic or strong germicide to the advancing border thus exposed; the galvano-cautery was the best, pure carbolic acid and strong tincture of iodine probably came next; transplantation of conjunctiva over the ulcer appeared useful occasionally. Though some cases were published as cured which would probably relapse, and though others went to universal leucoma in spite of all possible treatment, the results had been much better since the introduction of the cautery than before. Several old patients had done well and several young ones very badly. Allusion was made to the "marginal atrophy" of cornea recently described by Fuchs and to several other allied conditions of the cornea.—Mr. TREACHER COLLINS asked if there was any relation between the age of the patient and the rate of progress of the disease. In two cases which he had seen the ulceration of the cornea was most extensive, and yet the remaining opacity was not dense and remarkable good vision remained. In one case the patient developed a crop of vesicles on the cornea and some patches of infiltration, all of which cleared up upon his performing paracentesis and iridectomy.—Mr. J. B. LAWFORD related the case of a woman, aged 69 years, with no very definite specific history. In the right eye more than half the cornea was attacked; there was severe iritis, but not much pain, the temperature being normal. He cauterised the advancing edge and after a second application it healed. Shortly afterwards it broke out again and he then applied nitric acid without much good resulting. He then used solution of iodine daily, but it caused pain and did not do much good. Then the left eye became congested. An ulcer developed which he burnt with the cautery. The right eye had no unattacked cornea and it was vascular and cicatrised. The left was again cauterised and strong glycerine of perchloride of mercury was applied. After freely cutting away the edge and applying the galvano-cautery it healed, but again broke down and was cauterised. This was repeated and the patient still remained under treatment. In another case, that of a man, aged 46 years, healing was obtained after one application of the galvano-cautery.—Mr. W. LANG on one occasion after failure with the cautery did an iridectomy, when the ulcer healed and the case did well. Since then he had treated others in the same way with good results in all but one case.—Dr. A. BRONNER thought that there were two distinct classes of cases, one in which the ulceration was superficial and one in which it was deep.—Mr. SYDNEY STEPHENSON had published a case which occurred in a woman, aged 60 years, where the ulcer healed after two applications of the cautery. He then looked upon it as malignant, but this view he did not now hold. This disease seemed to occur about once in 17,000 cases, though more cases appeared to occur in some countries than in others. He thought the name Mooren's ulcer was a better term than serpiginous. Gifford had published a case in which the conjunctiva and sclera were involved in the ulcerative process, and last year an Italian observer isolated a bacillus which caused a disease when inoculated into the conjunctiva of rabbits.—The PRESIDENT stated that he had only seen a few cases, and he described one which occurred in a woman in which he advised an iridectomy, as it had when he first saw it resisted all kinds of treatment. The patient refused to have the

operation done and he subsequently transplanted a corneal flap with good result. The disease followed influenza. — Mr. R. E. BICKERTON asked if there was evidence of dacryocystitis in Mr. Nettleship's cases. — Mr. NETTLESHIP replied that lacrymal sac trouble was very uncommon in these cases. With regard to age and prognosis he had not worked it out, but he did not think that there was anything striking in this respect. He had never noticed vesicles on the cornea, neither had he found that the inhabitants of some countries were more liable to the disease than others. The cases cited by Mr. Lawford and the President certainly made the prognosis look bad, but he was sure that it was much better since the introduction of the cautery.

Dr. W. ERNEST THOMSON (Glasgow) read a paper on Keratitis in the Newly-born occurring after instrumental delivery and resulting in each case in an almost identical rare form of opacity. All the mothers had contracted pelves, and in the case of one with a conjugate of only two and three-quarter inches the delivery had been extremely difficult. Dr. Thomson saw two of these children very soon after birth, at which time three cornea out of the four presented opacities in the anterior corneal layers with dulling of the surface but no vascularity. There was in all some bruising of the lids and conjunctivæ. The subsequent result was peculiar, for while one cornea became progressively more infiltrated, and that uniformly, the other two quickly improved; but the opacities, instead of remaining as central nebulae, developed into white central vertical linear scars, with an adjacent area of much fainter haze. The third case had come under the care of Dr. Andrew Wilson at the fifth week. All signs of active keratitis had passed away, but an obliquely placed linear scar remained precisely similar in character to those in the other children. Dr. Wilson suggested that the cornea became buckled by the pressure of the forceps squeezing the eye against the nasal wall of the orbit. Dr. Thomson pointed out that such cases if seen late might be diagnosed as congenital corneal opacity of intra-uterine origin.

The following cases and card specimens were shown:—

Mr. A. HUGH THOMPSON: Sections of an Orbital Tumour (? Endothelioma, ? Adeno-sarcoma).

Mr. R. W. DOYNE: Tumour growing apparently from the Optic Disc.

Mr. ADAMS FROST showed some Eye Instruments used by Native Oculists in India which had been presented to the society by Major E. F. Drake-Brockman.

Mr. N. M. MACLEHOSE: Rodent Ulcer of the Upper Eyelid.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*Exhibition of Cases and Specimens.—Motor Localisation in the Lumbo-sacral Region of the Spinal Cord.*

THE first meeting of the eighty-first session of this society was held on Nov. 6th, Dr. A. G. MILLER, the President, being in the chair.

Dr. G. H. MELVILLE DUNLOP showed a rare case of Chloroma in a boy, aged three and a half years. Lympho-sarcomata usually originated in the periosteum of the cranium and the majority grew from the orbit. When such tumours were newly removed from the body they were of a bright green colour ("green cancer"). The boy was markedly anæmic, his eyeballs were so prominent that the lids could not be closed, and the palate was encroached on by growths of a purplish colour.

Dr. NORMAN WALKER showed (1) three cases of Lupus to illustrate the effects of light treatment; and (2) a Finsen lamp. Usually five applications were sufficient to produce a cure.

Mr. H. J. STILES showed (1) a girl, aged seven years, after operation for Plexiform Angioma of the Scalp; (2) a child, aged one year and nine months, with Unilateral Congenital Dislocation of the Hip; and (3) a child after operation for Tuberculous Disease of the Frontal Bone.

Various specimens were shown by Dr. ALEXIS THOMSON, Mr. STILES, and Dr. HARVEY LITTLEJOHN.

Dr. ALEXANDER BRUCE read a paper on the Motor Localisation in the Lumbo-sacral Region of the Spinal Cord. He had recently had the opportunity of making definite observations on two cases, which had shown that the motor-cells had a definite arrangement in each segment of the cord, so that one could determine by knowing the arrangement

and grouping of the cells to which segment it belonged. Nissl had shown that where a nerve-fibre had been cut or its muscle removed the corresponding nerve-cell underwent a constant "reaction at a distance" (Marinesco). The ordinary motor nerve-cell in the anterior cornu possessed dendritic processes and its granules were arranged in a more or less "tigroid" manner. When, however, the nerve-fibre had been cut and its distal part kept from uniting the nucleus of the motor cell wandered out from the centre and projected on the surface of the cell which lost its angles and appeared somewhat rounded: the body of the cell at the same time lost its characteristic appearance and within two weeks or so the protoplasm became finely granular. Such a method of observation allowed one to determine easily what the motor cells were which belonged to a particular muscle. There were three main groups of motor cells in the lumbo-sacral region of the cord—namely, (1) an antero-lateral group; (2) a postero-lateral or main group; and (3) a post-postero-lateral group which appeared earliest in the first sacral segment. All these nerve-groups were devoted to the muscles of the lower limb. There was also a fourth group—namely, a central or mesial group of cells situated close to the inner angle. It extended from the second lumbar to the second sacral segment and was very pronounced at the third and fourth lumbar segments. The antero-lateral group appeared at the second lumbar segment as a small group and gradually grew in size until it became a large group (with indications of further subdivision). It rapidly diminished in the first and second sacral segments, below which it could not be traced. The postero-lateral group extended from the second lumbar to the lower limit of the third sacral segment. The post-postero-lateral group extended from the first to the lower limit of the third sacral segment. In one case which Dr. Bruce had examined amputation of the leg above the knee had been performed. Here the calf muscles and the extrinsic and intrinsic muscles of the foot had been removed. On examining the cord the degeneration of cells (as shown by the Nissl reaction) commenced in the postero-lateral group below the fourth lumbar segment, as also in the post-postero-lateral groups (most marked in the first sacral segment). The antero-lateral, central, and mesial groups remained intact. The maximum reaction occurred at the first sacral segment, at which level the postero-lateral group was very large and where the post-postero-lateral group began to appear. Van Gehuchten and Nelis had described a case of amputation at the ankle where the reaction in the cells was limited to the post-postero-lateral group. If that be further confirmed then the post-postero-lateral column might be regarded as the centre for the intrinsic muscles of the foot, and the postero-lateral group from the fifth lumbar to the upper part of the third sacral segment inclusive as the centre for the muscles of the leg. The centres for the muscles below the knee must therefore be those in groups of nerve-cells situated between the upper limit of the fifth lumbar segment and the third sacral segment. In cases where the foot alone had been removed the small post-postero-lateral group of cells had undergone degeneration and demonstrated that that must be the centre for the muscles of the foot. In a second case a most extensive operation for tuberculous disease of the hip-joint and ilium was performed. The whole of the lower limb, acetabulum, and ilium and spines of the ischium were removed. The psoas, iliacus, pectineus, obturator internus, gemelli, and pyramidalis muscles were alone left and the pudic nerve received injury during a subsequent operation. One expected, therefore, that the only motor-cells in the lumbo-sacral region left intact would be those corresponding to the above-named muscles. On examination it was found that the area of degeneration was much more extensive than in the preceding case and that the whole of the cell-columns (with certain exceptions) were affected in the lumbo-sacral region. Degenerated cells began to appear as high up as the second lumbar segment, some cells in the posterior part of the antero-lateral group being affected. In the lower half of this segment the number of degenerating cells increased in the antero-lateral and postero-lateral groups. In the third lumbar segment the number of healthy cells in both the lateral groups rapidly diminished from above downwards. The central and mesial groups remained healthy. In the fourth and fifth lumbar segments practically all the cells in the lateral groups were degenerated. In the first sacral segment, however, normal cells again appeared and gradually increased in numbers in the antero-lateral group, but the postero-lateral group was entirely degenerated. Very similar

conditions were present in the second and third sacral segments. The undegenerated cells in these segments must therefore correspond to the unaffected muscles which were left (obturator, psoas, &c.). The anatomical distribution of the nerves in the lumbo-sacral region indicated that the psoas-iliacus was innervated from the antero-lateral and postero-lateral groups in the second and third lumbar segments chiefly, the obturator internus, and pyriformis (and perhaps the gemelli and quadratus femoris) from the antero-lateral group in the first and second sacral segments, the pyriformis from the second sacral. It was remarkable how far down the cord the nerve-cells for the hamstrings and external rotators of the hip descended. In the mesial group of the second and third sacral segment there were a considerable proportion of degenerated cells, while in the fourth segment the proportion of diseased to healthy cells was not nearly so great. This mesial group was the centre for the levator and sphincter ani and very probably for the striped muscles of the urethra. In the upper cervical region of the cord this mesial group was very small, but at the fourth and fifth cervical segments, where the nerves for the diaphragm arose, this group became very large. Probably this mesial group of nerve-cells supplied the muscles of the trunk both at the back and anteriorly. —Dr. BYROM BRAMWELL, Dr. NOEL PATON, and Dr. D. WATERSTON spoke, and Dr. BRUCE replied.

The following gentlemen were elected office-bearers for the session 1901-1902:—President: Professor T. R. Fraser. Vice-Presidents: Dr. James Andrew, Dr. Charles Underhill, and Dr. James Ritchie. Councillors: Dr. J. W. Ballantyne, Dr. George Kerr, Dr. K. M. Douglas, Mr. H. J. Stiles, Dr. A. G. Miller, Dr. Noël Paton, Dr. W. Russell, and Dr. Logan Turner. Treasurer: Dr. Harvey Littlejohn. Secretaries: Dr. Melville Dunlop and Dr. Alexis Thomson. Editor of Transactions: Dr. William Craig.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF PATHOLOGY.

#### *The Role of Protozoa in the Causation of Disease.*

A MEETING of this section was held on Nov. 1st, in the Royal College of Surgeons, Dublin, when Professor McWEENEY delivered the presidential address on the Role of the Protozoa in the Causation of Disease, with Special Reference to Malaria, Vaccinia, and Cancer. The address was illustrated with lantern and microscopical demonstrations. After some introductory remarks, in which Professor McWeeney set forth the reasons which had induced him to select the parasitic protozoa as the subject of his address, the speaker briefly explained the characters of the protozoal organism. The single cell of which it was composed must exercise the several functions which among the mesozoa were carried out by the groups of differentiated cells termed organs. It must move, feed, and multiply. The manner in which the protozoal cell discharged these functions was taken as the basis of classification. There were four great classes of protozoa—the rhizopoda, sporozoa, flagellata, and infusoria. The rhizopoda comprised the lowliest of living beings, amœbæ, formless lumps of protoplasm, moving by means of temporarily emitted pseudopodia, and differing from a human leucocyte only in their capacity for leading an independent existence. Amœbæ were normal inhabitants of the human intestine, where they seemed to have been first seen by Lambl in 1870. Lösch in 1875 ascribed dysentery to their parasitism. Since then an extensive literature had accumulated with reference to the causal relation in which amœbæ were supposed to stand to a certain form of dysentery termed "tropical" by Councilman and Lafleur in 1891. The speaker sketched the development of this doctrine, pointed out the sources of error that underlie not only some of the reputed findings of amœbæ in the faeces and in the pus of liver abscesses but also invalidate some of the reputed positive results of animal experiment, and concluded this part of the subject by saying that in view of the positive results recorded by Quincke and Roos, Kartulis, Kruse and Pasquale, and Zancanol from the injection of bacterially sterile liver-pus into the rectum of cats it was hardly possible to escape from the conclusion that the amœba coli was, by itself or in conjunction with bacteria, responsible for the causation of "tropical" dysentery. He did not know whether any case of this disease

had as yet been recorded in Ireland. He demonstrated a coloured screen picture of amœba coli. He then proceeded to describe the sporozoa, animals which in their adult stage appeared as amœbæ or else as more or less definitely-shaped protoplasmic masses, but which multiplied by division into a greater or lesser number of encapsulated germs, which from their resemblance to the reproductive bodies of the fungi were often spoken of as spores. They had recently been shown to possess a highly remarkable sexual method of reproduction. Passing over the gregarinidæ, as not found in the higher animals, he desired to lay stress on the next order, the coccidiidæ species of coccidium, which produced pseudo-adenomata in the bile-ducts of the rabbit, and plaque-like thickenings of the intestinal wall. Severely affected animals died from cachexia and anæmia. The parasite had two developmental cycles, both passed within the same host-animal. The mature animal consisted of a rounded, coarsely granular mass of protoplasm (schizont) lying within an epithelial cell of the rabbit's intestine or bile-duct. It split up into numerous sickle-shaped segments (merozoites) which became amœboid and infected neighbouring cells. At a certain period schizogony came to an end, and two varieties of mature parasite became differentiated, one larger, more evenly granular, the micro-gamete or female; the other smaller, more hyaline, the micro-gametocyte. Bi-flagellate bodies, the micro-gametes or spermatozoa, were emitted from the latter, each carrying with it a part of the nucleus. They penetrated into and fertilised the macrogamete, which increased greatly in size, assumed an oval shape and a doubly-contoured capsule, and, becoming detached from the epithelium, emerged with the faeces into the outer world as a "sporont"—the coccidium of the older writers. Soon its contents became divided into four sporoblasts, each of which assumed a tough membranous investment, and being set free by the decomposition of the outer cyst-wall was called a spore. Its destiny was to gain access to the alimentary canal of a fresh animal with the food and there to liberate the two sickle germs (sporozoites) which had been meanwhile formed in its interior. He alluded to the reduction of the chromosomes and the rest-körper or *corps de résiquat*. This interesting life-history had been revealed through the labours of L. and R. Pfeiffer, Labbé, Léger, Schaudinn, Siedlecki, and Simond. What made it the more interesting was that it ran strictly parallel to the life-history of the malarial parasites which had been recently so admirably cleared up through the work of Manson, Ross, Bignami, Grassi, and MacCallum. These parasites constituted the next order of sporozoa, the hæmosporidia. Professor McWeeney then proceeded to trace out the developmental cycle of the parasites of human malaria and to show that the phenomena were by no means isolated, but were strictly parallel to what had been shown to hold good for the coccidiidæ. The reproduction of the malarial parasite by sporulation in the circulation of the warm-blooded host was homologous with the schizogony of the coccidium in the rabbit's intestine. The sexual process of the malarial parasite differed from that of the coccidium in one feature only—the complication of a change of host, from the warm-blooded vertebrate to the cold-blooded invertebrate animal. This change was, of course, effected by the agency of the mosquito. He insisted upon this homology as bringing the malarial parasite into line with other forms of parasitic protozoa. Turning next to the third class of protozoa, the flagellata, the speaker detailed the main facts known regarding this parasitism in the lower animals. The best known of these parasites was the hepato-monas, or trypanosoma Lewisii, which was often found in the blood of the common wild rat. Through the courtesy of Professor Cunningham he had that morning examined the blood of 15 rats at the Zoological Gardens, and found the parasite in seven. He had brought one of the animals and now showed its blood, containing numerous actively motile fish-like parasites, each as long as three or four red blood discs, and provided with a long flagellum and an undulating membrane. He demonstrated a film stained by Romanowsky's method, showing the macro- and micro-nucleus stained red, and also the flagellum, an interesting factor for which he could not at the moment satisfactorily account. Although this parasite seemed harmless to the rat, a closely allied form, trypanosoma Brucei, had been shown to be concerned in the causation of surra, a disease of transport animals in India, and of the famous nagana or tsetse-fly disease in the warmer parts of Africa. He demonstrated a stained blood-film from a

guinea-pig, which he owed to the kindness of the late Professor Kanhack. As compared with those in the rat, some were blunter at the non-flagellate end. This did not hold good in all cases and he could see no other difference. In conclusion, the speaker referred to parasitic protozoa of uncertain biological position. *Piroplasma bigeminum* was a minute pear-shaped or oval speck of protoplasm, often occurring two together in the red corpuscles of the ox affected with parasitic hæmoglobinuria or Texas fever. The parasite was discovered a few years ago by Theobald Smith and Kilborne in the United States. They found that its propagation from one ox to another was effected by ticks. A unique feature of this transference was that it was carried not by the female tick that had actually sucked up the infected blood but by her progeny. Owing to the courtesy of Professor Mettam, principal of the Royal Veterinary College of Ireland, he was in a position to show specimens of the parasite found for the first time in Ireland by that gentleman in the blood of cattle suffering from red-water. Of still more uncertain position was the supposed parasite of vaccinia discovered by Guarnieri in the epithelium of the inoculated rabbit's cornea. Through the kindness of Dr. Gustave Mann of Oxford he demonstrated a preparation showing these bodies in almost every epithelial cell. The subject was one of some complexity and opinions were much divided as to the interpretation of the "bodies" in question. He preferred to reserve this part of the subject for a further communication later in the session. Lastly, the supposed protozoal etiology for carcinoma was a still more doubtful topic even than vaccinia. The tendency among recent Italian workers was to ascribe the disease to a blastomycete or yeast-form, which would, of course, be reckoned among the vegetable parasites. Sanfelice of Naples claimed to have obtained from fruit-juice an organism of this kind which had yielded positive results on inoculation. In England Plimmer had obtained from a rapidly-growing cancer a growth of an organism the biological nature of which appeared to be doubtful. The results of the inoculation-experiments seemed to the speaker to be far from convincing. The several varieties of cell-inclusions that had been so industriously worked up and identified at first with coccidia, then with blastomycetes, seemed to him to be susceptible of other explanations. He now demonstrated some of these inclusions. In this connexion it was interesting to note that ulcerated swellings exceedingly like tumours were developed on the roots of the cabbage and turnip as the result of the intracellular parasitism of *plasmodiophora brassicæ* (Wor), an amoeboid organism reckoned by some with the myxomycetes and by others with the protozoa. Cachexia and death of the host-plant were caused by this intracellular parasite, which thus formed an interesting analogy to what was sought to be established in the case of human cancer. He demonstrated sections of the affected roots showing the cells filled with the parasitic protoplasm and subsequently with the small spores, into which it divided.

The section then adjourned.

**BIRKENHEAD MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 8th, Dr. J. Pinkerton, the President, being in the chair.—Dr. Nathan Raw (Liverpool) read a paper entitled, "The Diagnosis and Treatment of Tuberculosis, with Special Reference to the Open-air Method." He said that consumption was the scourge of all civilised communities. Its ravages were world-wide; in Europe alone it was estimated that 1,000,000 people died annually from it. During the past 50 years the death-rate had in England been reduced 50 per cent. and he predicted that in future years it would be still further reduced. In Italy the disease had long been held to be infectious; even as far back as 1752 disinfection of the clothing of consumptive patients and lime-washing of the rooms and houses occupied by such patients were held to be necessary, and in Spain and in the south of France 100 years ago the same opinions existed. A great advance in their knowledge of the disease was brought about by the discovery by Professor Koch of the tubercle bacillus in the sputum and lungs of phthisical patients, and they now looked upon this bacillus as a constant factor in the causation of the disease. Dr. Raw discussed the question of the hereditary transmission of the disease. He held that there was little or no evidence to prove that such transmission did occur, but he considered this question of little importance as compared with infection after birth. In his

opinion there was very little specific tendency in children of tuberculous parents to become infected, except in so far that such children were not so strong as those of healthy parents, and therefore more susceptible to disease of any kind. The commonest way in which patients became infected was by the inhalation of tubercle bacilli. He then described the various modes of invasion of the disease, and in referring to the pleuritic forms stated that he was now by any means convinced that all cases of pleurisy were tuberculous, as was sometimes stated. He next discussed the diagnosis of tuberculosis and its treatment. The latter he divided into two heads: (1) preventive and (2) specific. Under preventive treatment he urged that phthisical patients must be taught not to spit upon the ground or floors of rooms, but should carry spittoons or some such arrangement in which the sputum could be collected and then destroyed either by treatment with disinfectants or by burning. The clothing and utensils used by such patients should be disinfected, and rooms which had been used by such patients should be disinfected, painted, and repapered before use by other individuals. He considered that an insufficient air-supply to the apices of the lungs was a very important agent in inducing phthisis, and he thought that all children ought to be taught to breathe properly, so as to expand their lungs thoroughly. In the open-air treatment the main object was to make the patient live out of doors as much as possible and also to improve his nutrition. If they fattened their patients then the disease might be left to take care of itself. At Nordrach patients were often in the open air for 10 hours every day, and that in spite of fog and cold. Excessive cold was not harmful even in advanced cases, as the results of treatment at Davos showed. The question of rest or exercise for such patients was a very vexed one, some authorities insisting upon absolute rest in the open air, others recommending gradually extended exercises. Complete rest with regular breathing exercises gave in many cases excellent results. A febrile condition with a temperature of 100° F. or over was an absolute bar to exercise. A three to six months' course of sanatorium treatment would generally arrest the disease. Pure air, an equable temperature, and a maximum of sunshine were the desired conditions, and given these cases would do as well in England as abroad. Specific medication had proved useless. Drugs could only be of use by helping to render the tissues more resistant. Dr. Raw mentioned some drugs and their combinations which had in his hands proved of service in the treatment of symptoms, including creasote or guaiacol as routine treatment. He laid great stress upon the importance of attending to the feeding-up of the patient, but he was not in favour of forced feeding as practised on the continent. In conclusion he said that an organised effort on the part of the medical profession, the health authorities, and the public must be made in fighting this disease. Healthy houses must be provided and insanitary areas must be swept away. He urged voluntary notification of the disease and voluntary removal of patients, municipal sanatoriums for curable cases, and isolation hospitals for incurable ones.—Dr. A. C. E. Harris, Mr. G. S. Stansfield, Dr. F. Johnston, Mr. F. Vacher, Dr. W. R. Dalzell, Dr. W. R. Floyd, and the President took part in the discussion which followed and Dr. Raw replied.

**BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.**—A meeting of this society was held on Oct. 30th, the chair being eventually taken by the incoming President, Dr. J. G. Douglas Kerr (Bath).—A vote of thanks was accorded to Dr. Frederic Bagshawe (St. Leonards) for his services as President during the past session.—The President then gave a short address, referring to the great improvements which had been made in bathing establishments at the different British spas during the past 20 years and to the impetus which had been given by the Royal Medical and Chirurgical Society to the study of balneology and climatology within the last six or seven years, specially mentioning the first part of the report published in book form by the society and the fact that the second volume of the report would be issued shortly. There was a possibility, he said, that a tour of inspection through the British health resorts might be arranged by the society during the ensuing session.—Mr. King Houchin (London) read a paper on the Treatment of Syphilis by Inunction. He said that the treatment of syphilis as practised at Aix-la-Chapelle could be, and was, carried out at most of the British

spas and even in London. He had discovered after some five years' practical experience that satisfactory results could be obtained in London. During treatment great care of the teeth should be taken and the patient should use a mouth-wash of chlorate of potash, with or without some mild astringent, night and morning and after meals. The patient should remain for 20 minutes or half an hour in a hot bath, preferably mineral, the temperature of the bath being from 98° to 100° F. The preparation commonly used for inunction was the unguentum hydrargyri (B.P.). After the bath a portion of the body was selected for the inunction. The method he usually followed was to divide up the body into five sections so that in five days the whole of the body surface had been subjected to inunction. This should be repeated on consecutive days, if possible, until from 25 to 30 applications had been made. This constituted "a course," which should be repeated in six months' time, two or three courses usually being sufficient for all ordinary purposes, and the patient might then be considered to be cured. He advised the inunction to be carried out by a glass rubber. The treatment had the following special advantages for patients who were either quite unable to leave their homes or for whom it was undesirable to do so: (1) the system could be saturated to toleration; (2) digestion was not interfered with; (3) a much larger dose of mercury could be tolerated by the skin than by the mouth; (4) mercurial cachexia was seldom seen under this method of treatment; and (5) the patient, on the contrary, usually gained weight, colour, and nutrition.—Dr. Fortescue Fox (Strathpeffer) suggested that it might be possible to promote the absorption of mercury by connecting the rubber with the pole of a battery. There were other chronic disorders (not syphilitic) that derived benefit from mercurial inunction—for example, some forms of dyspepsia and malnutrition.—Dr. Sansom (London) said that from personal experience of cases thus treated he considered that the institution managed by Mr. Houchin in London on the lines of those at Aix-la-Chapelle and Wiesbaden had supplied a distinct want. He would include in the list of cases to be thus treated those of syphilitic disease of the cerebral arteries.—Dr. G. A. Leon (Sidmouth) said that the paper was of especial interest to the society as it indicated how treatment usually carried on abroad could be made successful at any health resort in England. He had visited Aix-la-Chapelle and preferred in some ways the methods there. He thought that the hand was the best vehicle for inunction and that treatment at a spa with the discipline there was often necessary and generally useful. In tertiary cases several courses of daily inunction were necessary in many instances, the course consisting of from 50 to 150 days. In an early case of secondary disease four courses spread over two years, with from 30 to 40 inunctions in each course, was necessary to be safe. A more astringent mouth-wash than chlorate of potash should be used, such as dilute acetate of lead and alum. In advanced tertiary cases iodide of potassium was most necessary to arrest the disease until the mercurial inunctions could have their effect. He agreed with Mr. Houchin in attaching no special importance to the sulphur waters, but a hot bath was requisite before inunction.—The President said that at Aix-la-Chapelle and at Bath a very large number of applications were found necessary in tertiary syphilis—many more than were recommended by Mr. Houchin. The temperature of the bath was never allowed to exceed 95°. Artificial rubbers had been tried but had been discarded and the hand method had shown better results. He considered that the discipline entailed by residence at a spa was a great factor in assisting the cure.

#### ROCHDALE AND DISTRICT MEDICAL SOCIETY.

A meeting of this society was held on Nov. 7th.—Mr. R. Burdett Sellers gave the presidential address on an Acute Infectious Disease. After referring to the diminished death-rate, notably from zymotic diseases and phthisis, Mr. Sellers said that there was one very common disease which showed little reduction in its death-rate—viz., pneumonia. This was an acute infectious disease caused by the diplococcus pneumoniae of Fraenkel. The pneumococcus, however, might cause other conditions, as empyema, peritonitis, ulcerative endocarditis, &c., which might be primary or secondary to an attack of pneumonia. The coccus was often present in the saliva of healthy individuals. They had in and about them the organisms of many diseases only waiting an opportunity for developing

malignant action. Such opportunity came with impaired vitality due to chill, fatigue, or other cause. Leucocytes were increased in the pyrexial stage of pneumonia and were diminished with the critical fall of temperature. The crisis was probably due to the formation of an antitoxin in the blood (Washbourn). The serum of patients convalescent from pneumonia was said to have protective power. Non-alcoholic cirrhosis of the liver might be due to an antecedent attack of pneumonia, judging from liver changes during an attack of the disease. With regard to treatment pneumonia could not be cut short by any known means. The routine saline treatment consisted of the administration of laxatives, with a liquid unstimulating diet and complete rest in an airy room at a temperature of above 60° F. with a proper degree of moisture. Death was generally due to heart failure, hence depressing treatment should not be employed. Special circumstances might call for the use of quinine in full doses, or, in cases of low type, tincture of perchloride of iron. It was unwise to reduce the "normal temperature of pneumonia" (103° or 104°) unless delirium or other condition called for interference. In hyperpyrexia the cold bath or similar remedy was the only measure of any use, large doses of quinine being auxiliary. The value of poultices was doubtful and they restrained respiratory movements. Ice applications might relieve pain. Strychnine and caffeine were most useful to combat cardiac failure. Oxygen was valuable where the respiratory surface was small. Dr. G. Balfour's chloral treatment was also described by Mr. Sellers.—A discussion followed the address in which Mr. G. W. Malin, Mr. W. Stanwell, Dr. D. Richmond, Dr. A. Wallace, Dr. A. B. McMaster, and Dr. W. Hodgson took part.—Mr. Sellers received a hearty vote of thanks for his interesting address.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—The annual general meeting of this society was held on Nov. 8th, Mr. Mayo Collier, the President, being in the chair.—Mr. Lennox Browne showed the Nernst Electric Lamp as one giving a far whiter light than any in present use.—The President showed (1) a case of Malignant Disease of the Pharyngeal Wall which was inoperable, and it was proposed to submit the patient to electrical treatment by Dr. J. Macintyre of Glasgow; (2) a case of Abscess of the Maxillary Antrum associated with Facial Paralysis which had subsided promptly after surgical treatment; and (3) a case, in the person of a surgeon, who was present and spoke on his own case, in which asthma had been relieved after the removal of nasal polypi. Mr. Chichele Nourse showed a case in which a Laryngeal Growth had Disappeared after the removal of Nasal Polypi.—Mr. Lennox Browne remarked on these last two cases and said that although they were by no means unique it was useful to record them, and he trusted that such cases would be always brought forward in view of the fact that quite recently doubts had been thrown on the importance and frequency of asthma and other diseases arising as nasal reflexes, notwithstanding that they had been accepted by observers of repute all over the world.—Mr. John Bark, while accepting these cases as reported, reminded the Fellows that not all were cured.—Dr. P. H. Abercrombie showed a case of Black Tongue from which Dr. Wyatt Wingrave had prepared microscopic slides and furnished a bacteriological report.—Mr. Lennox Browne made a short communication on the Preliminary and After-treatment of Operations on the Mouth and Fauces, insisting on (1) preliminary antiseptic washes; (2) sterile instruments; (3) complete rest of the parts and of the body generally after operation; (4) the use of mouth-washes by means of the throat-syringe instead of gargles; and (5) the non-administration of internal drugs, such as the bromides, which might cause skin eruptions liable to be mistaken for symptoms of septic infection.—Remarks were made by Dr. Haslam, Dr. Wyatt Wingrave, and the President.—Dr. J. Macintyre then delivered his presidential address on the Application of Physical Science to the Surgery of Diseases of the Throat and Nose. This was illustrated by the exhibition of many instruments and by lantern photographs. The following office-bearers were elected at this meeting: President: Dr. Macintyre (Glasgow). Vice-Presidents: Dr. Greville MacDonald, Dr. Walton Browne (Belfast), and Dr. J. D. Hillis (Dublin). Council: Mr. Mayo Collier, Dr. Culver James, Mr. Claud Woakes, Dr. Atwood Thorne, Dr. J. M. E. Sealiff (Brighton), Dr. R. H. Woods (Dublin), and Dr. W. H.

Kelson. Treasurer: Mr. Lennox Browne. Secretaries: Mr. Chichele Nourse and Dr. Abercrombie.

**CARDIFF MEDICAL SOCIETY.**—The ordinary monthly meeting of this society was held on Nov. 7th, Dr. D. R. Paterson, the President, being in the chair.—The following new members were elected: Dr. Evelyn J. Evatt and Dr. R. Cameron (Cardiff) and Dr. T. J. Jenkins (Pentre).—The meeting was devoted to a discussion on Infant Feeding.—Dr. A. P. Fiddian, who opened the discussion, considered the subject under the heads of (1) the feeder—mother or nurse; (2) the infant; and (3) the food. In regard to (1) he held that devotion to duty should take the leading place, affection adding sweetness and acceptability to the discharge of it. He would allow of no arrangements for amusement or ease that would interfere with the infant's needs. He described the qualities of a good nursing-woman and some physical defects that rendered her inefficient. He mentioned the instance of a few women who took alcohol in moderate quantities for the arrest of the lacteal secretion when weaning, and called attention to the need of a scientific inquiry into the effects of moderate amounts of stimulant on the formation of milk. 2. The great variations in children were discussed, some failing to thrive during the earlier months, child after child in the same family, while in others there was a tendency to excessive adipose tissue with a minimum of feeding. 3. This part of the subject was rendered instructive by illustrative standards showing the composition of milk lent by the Aylesbury Dairy Company and the Friern Manor Dairy Farm, Limited, the former including the milk of the goat, ass, and mare, as well as human and bovine milks. The Gaertner process and other methods of humanising milk were discussed. In regard to sterilisation, Dr. Fiddian's own observations had not supplied him with any instances of scurvy from the use of sterilised milk, but condensed milk had done so.—The President followed, and in the course of his remarks called attention to the Walker-Gordon laboratories in America and in a few English towns where the food was prepared according to the medical attendant's prescription.—A long and interesting discussion followed, in which the following gentlemen took part: Dr. Ewen Maclean, Dr. E. Walford, Dr. R. Prichard, Dr. H. G. G. Cook, Dr. Mitchell Stevens, Dr. Eldon Pratt, Mr. W. B. C. Treasure, Dr. William Sheen, Dr. A. E. Taylor, Dr. H. H. Tidswell, and Dr. G. N. W. Thomas.—Dr. Fiddian replied.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY.**—The second meeting of the forty-sixth session of this society was held on Nov. 1st, Dr. Thomas C. Meggison, the President, being in the chair.—After the election of several new members Mr. G. Chisholm Williams read a paper on High Frequency Electrical Currents in the Treatment of Certain Diseases. The paper was divided into two parts, one dealing with the method of production from the electric-light mains, Wims-hurst machine, or accumulators. A complete description of the apparatus required was given and the various ways of utilising the currents by auto-conduction, auto-condensation, resonator, or bi-polar method, were described and demonstrated. The second part of the paper dealt with the following diseases: pulmonary tuberculosis, tuberculosis of joints, tuberculous laryngitis, lupus, eczema, psoriasis, rodent ulcer, malnutrition from rickets and dyspepsia, sciatica and neuralgia, and diabetes. Cases and notes of the above were shown or read.—A discussion followed in which the following took part: the President, Dr. R. E. Scholefield, Dr. C. H. Hartt, and Dr. G. Herschell.—A conversazione will be held after the meeting on Dec. 6th.

**HORSE AMBULANCES.**—At the meeting of the Manchester Infirmary Board on Oct. 28th it was stated that horse ambulances had been established by the Watch Committee for use in case of accidents or illness in the streets. They will be at one of the police stations, will be available by day or night, and may be summoned by telephone. It is intended also to take to the hospitals, without charge, any cases of illness or serious accident occurring at works. The charge for the removal of cases from private houses to the various hospitals will be at the discretion of the chief constable. It was stated, however, that it would be at the rate of 7s. 6d. up to a mile, 10s. over a mile, and there would be a special rate outside the city.

## Reviews and Notices of Books.

*Pulmonary Tuberculosis: its Prevention and Cure.* By CARLO RUATA, M.D., Professor of Materia Medica at Perugia. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1901. Pp. 143. Price 3s. net.

THIS little work, written in English by Dr. Ruata, who was one of the Italian delegates to the British Congress of Tuberculosis, has for a chief feature its warm advocacy of antiseptic inhalations in the treatment of pulmonary tuberculosis. Of the many aromatic volatile substances suitable for this purpose the author prefers a combination of chloroform and creasote dissolved in alcohol, administered by means of a wire-gauze mask covering both nose and mouth. The use of such a mixture in oro-nasal inhalers has been in vogue with English physicians for nearly 20 years, but not, generally speaking, in the uninterrupted way, continued over long periods, which Dr. Ruata considers as essential to success. He is, however, careful to point out that it is to be regarded only as a useful adjunct to, and in no sense as a substitute for, the open-air treatment, which the patients whose cases he describes were at the same time made to adopt as far as possible. The benefit derived was in all of these instances very great and in many a complete cure was effected.

In regard to the sanatorium treatment, it is interesting to note that Dr. Ruata recognises the claim to priority of the English physician, Dr. George Bodington of Sutton Coldfield in Warwickshire. He it was who first established the value of the open-air treatment and clearly enunciated rational rules for the management of consumption. His teachings were set forth in a pamphlet published in 1840 and were met with such a storm of disapproval and abuse that its author, who was in consequence looked upon as little short of a lunatic, was obliged to abandon his method of treatment and ended by converting his hospital for consumption into a lunatic asylum. Dr. Ruata has little faith in the various serums hitherto tried as curative agents, and none in the swallowing of drugs, which only relieve symptoms and cannot stop the disease. He is a believer in the transmission of tuberculosis by heredity, as well as in Koch's statement that the disease cannot be contracted by man from drinking the milk or eating the meat of tuberculous cattle; and he gives in an appendix in support of these views some very striking statistics, which, however, involve such complicated considerations that the conclusions which he draws from them are not likely generally to be accepted as proven.

We trust that Dr. Ruata, who, by the way, has lately been defending us manfully in regard to the Transvaal war against the Italian pro-Boers, will find many readers for his sensible and practical little book in this country.

*Studien über den Echinococcus Alveolaris sive Multilocularis.* (Studies upon the Echinococcus Alveolaris or Multilocularis.) By N. MELNIKOW-RASWEDENKOW. Jena: Gustav Fischer. 1901. 8vo. Pp. 296. With six plates and 94 figures. Price 16 marks.

THIS elaborate research into the subject of echinococcus multilocularis—or, as the author prefers to call it, echinococcus alveolaris—is based upon a personal investigation of 101 specimens collected from Russia, Germany, Switzerland, and Austria. Dr. Melnikow-Raswedenkow first gives a full account of the specimens, in which he also includes clinical particulars whenever possible. A detailed microscopical examination is also often appended. In regard to the parasitology the author holds that the parasite causing the multiloculated disease is distinct from that causing the uniloculated. The former is not brought about by the behaviour of the tissues in relation

to the parasite but is due to the parasite itself. Separate chapters are next devoted to the general and special pathology of the disease. The primary disease is most often found in the liver. The secondary deposits may be found in various organs and are due to the embryos being carried to them either by the blood or the lymph stream. When the embryo arrives from the alimentary canal it produces a many-chambered chitinous coil in which both ovoid embryos and scolices are produced. In the uniloculated variety scolices only are found. The embryos may penetrate into the tissues by amoeboid movement. Some of these embryos may then develop into chitinous cysts in which new embryos are eventually found or they may be converted into sterile cysts. Not infrequently the embryos are attacked in the animal tissues by phagocytes and are destroyed. The toxins manufactured by the parasite stimulate the tissues to greater growth and granulation tissue may form. Dr. Melnikow-Raswedenkow has also investigated echinococcus alveolaris in animals and he found the changes produced in the tissues to be the same as those in man. The intermediate host plays a relatively limited rôle in the case of the echinococcus alveolaris owing to the diminished resistance of the scolices which arriving in the alimentary canal are no longer able to develop. In discussing the geographical distribution, the author says that the disease occurs more frequently in Russia than elsewhere. After reviewing the literature of the subject he finally discusses the symptoms, etiology, and treatment, and appends a useful scheme to be used in the anatomical and experimental investigation of multiloculated hydatid disease. The disease is distinctly dangerous to life; its treatment is mainly surgical. Those interested in hydatid disease will find Dr. Melnikow-Raswedenkow's monograph in every sense an excellent one.

*Practical Text-book of Plant Physiology.* By DANIEL TREMBLY MACDOUGAL, Ph.D., Director of the Laboratories of the New York Botanical Garden. London: Longmans, Green, and Co. 1901. Pp. xvi., 325. Price 7s. 6d.

THE teaching of the physiology of plants has been somewhat neglected in this country; indeed, even in places of more advanced education this all-important branch of botany has not found, in some instances, a place in the curriculum until comparatively recently. Now, however, the botanists of examining bodies insist upon its importance, so that it is becoming more widely taught as time goes on. This being so, the appearance of the work before us is most opportune, for teachers are in want of a book which covers more than the mere elementary facts, but not so advanced as Pfeffer's Physiology of Plants, for example. For their needs Dr. Macdougall's work will be found to be an excellent book; and also for their students who already have become acquainted with the more important facts of the structure, &c., of plants, besides possessing a knowledge of chemistry and physics without which many of the phenomena of plant-life will be but very imperfectly understood.

As to the aim and scope of the work, we cannot do better than quote what is said by the author in his preface. "The arrangement of the subject ..... is an effort to place before the student a method by which a working knowledge of the physiological complex of the plant may be acquired. The disposition of the subject matter entailed by this treatment consists, briefly stated, in the study of the particular functions and properties of the organism, in connection with the agencies and forces which influence or initiate them, and a consideration of the general processes of plant-life." The work, as is indicated by the title, is a practical one, but, as the author states, "a discussion of the principles of the subject is interwoven with the directions for practical demonstration in order to afford means of interpretation of the experimental results secured."

The volume contains much which may prove of interest to medical men—for example, the action of poisons and anæsthetics on the streaming movements exhibited by the protoplasm in the cells of the leaf of *Elodea*, and the hairs on the stamens of *Tradescantia*, for instance. Thus if such a structure is subjected to the action of the vapour of either ether or chloroform the movements stop entirely after a short time; the rotation is resumed, however, on passing over air provided, of course, the anæsthetic has not been allowed to act for too long a time. Again, carbonic acid gas acts in much the same manner as ether, all movements in a cell being stopped when the gas is passed over. The time taken to stop the motion of the protoplasm naturally varies in different plants; and further, as a human being may take, by gradually increasing the doses of a poison, what normally would be a fatal quantity, so also it is possible to educate, as it were, the protoplasm of a plant, for if a staminal hair of *Tradescantia* is placed in an atmosphere containing carbon dioxide which is insufficient in quantity to stop the protoplasmic movements and after a time is replaced by an atmosphere containing a higher percentage of the carbonic anhydride, it is found that if the process is continued it is possible to have the movements going on in the pure gas.

The work is illustrated by 159 figures; the paper, print, and "get up" are extremely good, and the work will not fail to prove of great value.

*Verhandlungen der Siebzehnten Versammlung der Gesellschaft für Kinderheilkunde. (Transactions of the Seventeenth Meeting of the Society for Children's Diseases.)* Edited by Dr. EMIL PFEIFFER. Wiesbaden: J. F. Bergmann. 1901. 8vo, pp. 260. Price 8s.

SEVERAL subjects of considerable practical interest are included in these Transactions. Under Nervous Diseases Dr. Falkenstein (Königsberg) contributes a valuable paper on Amaurotic Idiocy, in which he details and analyses a case and reviews the literature of this rare disease. Dr. Siegert (Strassburg) gives an account of the Pathology and Treatment of Idiocy due to Infantile Myxœdema. When considering the diagnosis he speaks of the alteration in the bones of the skeleton and of the value of radiography. Thyroid treatment produces a great improvement in many cases and a cure in a few. Professor Heubner (Berlin) details a very interesting case of Multiple Gliomata of the Spinal Cord in a Child, aged six years, complicated with Meningitis and Hydrocephalus. Dr. Fischbein (Dortmund) in a paper on Laryngismus Stridulus attaches an unusual importance to the dietetic treatment.

Among diseases of the organs of digestion a valuable paper is contributed by Dr. Ungar (Bonn) on Chronic Peritonitis and Tuberculous Peritonitis. The author almost doubts the occurrence of a chronic peritonitis apart from tuberculosis. He is not as enthusiastic upon the value of the treatment of tuberculous peritonitis by abdominal section as are some writers, but he recommends it in the severer cases. There are various papers on the artificial feeding of infants by several authors—viz., Dr. Biedert, Dr. Adolph Schmidt, Dr. Bachhaus, and Dr. Oppenheimer, whereas Dr. Conrads discusses the reasons why mothers are not able to nurse their children. Dr. Biedert's article upon the Establishment of Institutions for the Feeding of Infants and Children is certainly worthy of attention. He gives approximately what would be the cost of such an institution and its maintenance. In the discussion on this subject some difference of opinion was expressed. Professor Heubner also contributes a somewhat technical paper on Infantile Atrophy, and Dr. Camerer, jun. (Stuttgart), continues the account of an investigation into the chemical composition of the infant's body based on a case in which the analysis was performed by Dr. Söldner. Dr. v. Ranke (Munich) advocates the excision of the diseased

tissues in Noma and relates three cases successfully treated in this way. Dr. Rey (Aachen) speaks of Cystitis as a Cause of Retention of Urine in Children under Three Years of Age. He looks upon it as a contra-indication to the operation for phimosis in these cases.

Dr. Hochsinger (Vienna) gives an elaborate and interesting account of Phalangitis due to Congenital Syphilis. Fifty-five of his cases occurred during the first year of life and nine at a later period. He says that the affection is one of the most curable of those occurring in early hereditary syphilis. Besides the paper on Tuberculous Peritonitis referred to above there are two other contributions to the subject of tuberculosis—namely, on its Relation to Scrofula and its Prophylaxis. Professor Ponfick (Breslau), in a very interesting paper, concludes that Scrofula is a comprehensive term, including several well-defined processes too long grouped together. He recognises three such groups in which the inflammatory affections are due to (1) pyogenic microbes, (2) the tubercle bacillus, and (3) a combined infection of these micro-organisms. Dr. Feer (Bâle) enumerates the mostly well-known measures for the Prevention of Tuberculosis in Children.

*Morbus Hungaricus. (The Hungarian Disease.)* By Dr. TIBERIUS VON GYÖRY. Jena: Gustav Fischer. 1901. 8vo, pp. 190. Price 5 marks.

THIS elaborate work by Dr. von Györy is largely of anti-quarian interest. He has collected together the writings upon this disease down to more recent times, and he closely analyses the views advanced in them. The subject matter is chiefly discussed under the headings of (1) the real nature of the morbus Hungaricus; (2) its confusion with other diseases; (3) the locality and period of its epidemics; (4) the prophylaxis; and (5) the treatment. From the modern point of view the chapter in which Dr. von Györy ably discusses what was the real nature of this disease is of the greatest interest. He concludes that the morbus Hungaricus was none other than typhus fever. He discusses and finally sets aside the objections which might be raised against this view, such, for instance, as the occasional absence of the rash and the presence of diarrhoea. The medical bibliographer will undoubtedly be greatly indebted to Dr. von Györy for his admirable research into the morbus Hungaricus, but the work hardly belongs to the category of books which can be of real practical value to the busy modern student of medicine.

#### LIBRARY TABLE.

*Hong-Kong. Report of the Medical Officer of Health on the Epidemic of Bubonic Fever (Plague) during the Half-year ending June 30th, 1901.* Hong-Kong: Noronha and Co. 1901. Pp. 35.—Dr. Francis W. Clark, medical officer of health of Hong-Kong, states that the total number of cases of plague reported during the half-year was 1488, of which 26 were among Europeans and 1415 among Chinese (including 308 dead bodies found lying in the streets or floating in the harbour), the remaining 47 being among other Asiatics. A large number of Chinese, however, left the colony as soon as they felt at all unwell, some of whom showed unmistakable signs of the disease on arrival in Canton and its neighbourhood. The total number of deaths recorded during the half-year was 1417, of which nine occurred among Europeans, 1376 among Chinese, and the remaining 32 were those of other Asiatics. The death-rate among the Europeans was therefore 34.6 per cent., while among the Chinese it was 97.2 per cent., and among the other Asiatics 68.1 per cent. The disease increased rapidly from the end of March to the middle of May concurrently with the increase in the atmospheric mean temperature, but as soon as the mean temperature exceeded 80° F. the

disease suddenly decreased. The number of rats collected and paid for was 48,000.

*New South Wales. Twelfth Report of the Metropolitan Board of Water-supply and Sewerage.* Sydney: W. A. Gullick. 1901. Pp. 89. Price 5s.—This report on the water-supply and sewerage of Sydney relates to the period extending from July 1st, 1899, to June 30th, 1900, and in addition to the 89 pages of letterpress contains a map, photographic views, and folding plates of graphic diagrams. The average daily consumption of water per head of estimated population supplied was 41.62 gallons, as against 41.72 gallons during the year 1898-99. The average daily supply was 19,885,953 gallons, and the estimated population supplied was 478,000. The Nepean, Cordeaux, and Cataract rivers are the sources from which the Sydney Waterworks are supplied. The combined catchment areas of the three rivers enjoy a copious and regular rainfall and extend over an area of 354 square miles. The water is brought to Sydney by courses having a total length of about 63 miles. A report on the health of Sydney by Mr. T. M. Kendall, medical adviser to the board, shows that during 1899 there were 795 cases of typhoid fever reported, with 87 deaths. The sewerage system is being remodelled so that no sewage shall be discharged into Sydney Harbour, but that all shall be conducted to two outfalls, one leading into the open sea and the other on to a sewage farm.

*Zur Lehre von der Blutzirkulation in der Schädelhöhle des Menschen namentlich unter dem Einfluss von Medikamenten. (Intracranial Circulation in the Human Subject, with especial reference to the Influence of Medicines.)* By Dr. HANS BERGER. Jena: Gustav Fischer. 1901. Pp. 78. Price 5 marks.—After a general survey of the history of the subject and a description of the methods of investigation hitherto adopted, Dr. Berger proceeds to an account of his own observations made on a patient who had been trephined at the posterior upper angle of the left parietal bone in consequence of severe symptoms of intracranial pressure. The aperture in the bone measured about two inches by three inches and was covered with a gutta-percha cap which carried a recording apparatus. Dr. Berger discusses three forms of cerebral movements: (1) that due to the arterial pulse; (2) that due to the respiration; and (3) the so-called vasomotor movements or undulations. The medicinal substances employed were amyl nitrite, camphor, digitoxin, caffeine, cocaine, ergotin, morphia, and hyoscin. A number of tracings are given showing the effects produced.

*Report of the Edinburgh and East of Scotland South African Hospital.* Edited by DAVID WALLACE, C.M.G., F.R.C.S. Edin., and FRANCIS D. BOYD, M.D., F.R.C.P. Edin. Edinburgh: Oliver and Boyd. 1901. Pp. 193. Price 5s. 6d.—The reviewer is apt to echo the Wise Man and to exclaim, "Of the making of many books there is no end," when he considers the number of books which have appeared dealing with the medical aspects of the South African war. But, as the preface to the present volume points out, there is a reason for publishing the records of the civil hospitals at the war. These organisations formed a special feature of the war and by a record of their work, their difficulties, and the way in which those difficulties were met guidance for the future may be had. The hospital was stationed at Norval's Pont and began work at the beginning of May, 1900, although regular work as a hospital with beds was not commenced until May 29th when 96 patients were admitted. The hospital then consisted of 100 beds, but by July it had been increased to 150. The wards consisted of four huts containing respectively two wards. Water was obtained from a spring two miles away at first, but later a tube well was bored which gave a good supply. The drinking water was all filtered through Pasteur-Chamberland filters. The volume contains reports upon both the medical and the surgical cases. The latter, as might be expected, were nearly all cases of

bullet or shell wounds. The reports of these cases in no way differ from those of cases treated at other hospitals in the war. All the shell wounds but one were septic, while the bullet wounds were as a rule aseptic. The x rays were found to be very useful in the locating of bullets and in no instance was a soft-nosed bullet found. The report upon the medical cases is nearly entirely a very interesting essay upon enteric fever. It is written by Dr. Francis Boyd, the surgical report having been supplied by Mr. David Wallace and Dr. George L. Chiene. The report upon enteric fever merits careful study, and with regard to inoculation Dr. Boyd is, as is only natural, cautious. He says: "The outlook for inoculation is hopeful. .... While we cannot consider an inoculated person immune, it is to be hoped that we can consider that he has got an increased power of resistance." Apart from enteric fever only three cases of pneumonia were observed, one of which, in a native, was complicated with dry gangrene of the feet which were amputated. The whole report is well worth reading and the editors are to be congratulated upon the amount of interesting matter which they have supplied.

## JOURNALS AND MAGAZINES.

*Midland Medical Journal*.—Birmingham now possesses two monthly medical periodicals. The *Birmingham Medical Review* has reached the mature age of Vol. L., whilst the first number of the *Midland Medical Journal*, the official organ of the Birmingham and District General Practitioners' Union, bears date November, 1901. The newcomer consists of 20 pages in double columns and makes a very promising appearance. It opens with a "Fore-word" by Sir James Sawyer, followed by three original articles—namely, on Pulse Taking, by Dr. Arthur Foxwell; on Cerebro-Spinal Meningitis, by Mr. E. E. Hamilton Williams; and on Right Hemianæsthesia, by Dr. T. Sydney Short. A leading article, a lengthy report of Mr. Victor Horsley's address delivered before the Practitioners' Union on Oct. 24th, correspondence, and miscellaneous literary matter complete the number. There is an editorial committee consisting of eight members, the editor being Mr. James Neal, L.R.C.P. Lond., M.R.C.S. Eng. The annual subscription is 3s. 6d., and all communications (orders included) should be addressed to the Editor, 610, Coventry-road, Birmingham.

*Scottish Medical and Surgical Journal*.—The opening article of the November number is a clinical lecture by Dr. D. Berry Hart (Edinburgh) on Four Cases of Fibromyoma Uteri: the operations performed were respectively curettage, removal of fibroid polypus, double oöphorectomy, and abdominal hysterectomy. Dr. Noel D. Bardwell of the Sanatorium, Banchory, Aberdeenshire, contributes a short paper upon Dietetics in Pulmonary Tuberculosis. He considers that in some cases too much food is given, and describes an experimental investigation in which he took part. The patients were in Brompton Hospital and had three meals daily made up of—meat, seven ounces; bacon, two ounces; one egg; milk, three pints; butter, three ounces; bread, seven ounces; sugar, one ounce; pudding, five ounces; and vegetables, six ounces. It was found that the patients thrived better on this diet than on a more liberal one, containing six or seven pints of milk and 12 ounces or more of meat.

*Grèce Médicale*.—Both ancient and modern medicine supply subjects for the September number. The archaeological articles are the following: Medicine in the Time of Esculapius, by Dr. P. Kavadias of Athens; the Tomb of Esculapius, by Dr. J. Svoronos of Athens; the Therapeutics of the Homeric Age, by Dr. Sp. Manghinas of Athens; and Prescriptions contained in the Manuscripts preserved on Mount Athos, by Dr. Sp. Lambros of Athens. Dr. Foustanos of Syra,

editor of *La Grèce Médicale*, also edits *Iatpich Hproodos*, a much larger journal published almost entirely in Greek.

The *Cornhill Magazine* for November is quite up to its usual form and that is saying a great deal. The Rev. H. G. D. Latham describes the difficulties of managing a club for the class which ultimately grows into the Hooligan or possibly has already done so, but it is only by such means that the budding plant will be checked. Mr. C. W. James writes a delightful article upon "Music in Fiction." He quotes from "Henrietta Temple" Lady Bellairs's charming remark about Pasta: "She shall sing at all my parties. .... I will try to ask her to dinner once at least. I do not like singers and tumblers at dinner." We all remember Mr. Osborne, "Lords indeed!—why at one of her swarveys I saw one of 'em speak to a dam fiddler, a fellar I despise." Lady Bellairs's language is more refined, but the beautiful high-bred sentiments are the same. We should like to remind Mr. James of another musical incident and that is in Miss Braddon's "Hostages to Fortune," where the wicked but accomplished stockbroker plays Beethoven's symphonies upon a harmonium, the C minor and the Eroica! And this on a harmonium of a date just before the Franco-German war. "The Londoner's Log Book" pursues its sparkling tenor and the whole number is a good one, the article on Newman being of special interest. Light literature which really is literary is a desideratum for hard-worked professional men and the reading of magazines like the one before us will lighten the busy practitioner's toil.

## Analytical Records

FROM

## THE LANCET LABORATORY.

TABLOIDS: (1) QUININE AND CAMPHOR; AND (2) QUININE, BELLADONNA, AND CAMPHOR.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, LONDON, E.C.)

THE formula of the former tabloid is as follows: quinine bisulphate one grain and camphor one-fifth of a grain; and of the latter as follows: quinine sulphate quarter of a grain, extract of belladonna one-eighth of a grain, and camphor a quarter of a grain. They are suggested as of value in the treatment of the early stages of catarrh.

## AQUAFORM.

(ARTHUR AND CO., 69, BERNERS-STREET, LONDON, W.)

Aquaform is a pink, slightly fluorescent fluid with a pungent smell not unlike formaldehyde. It contains di-oxy-methylene hydrate. It is stated to be a useful application for perspiring hands, giving relief to this annoying affection. We have given the preparation a trial with very encouraging results.

(1) CROWN BEER; AND (2) CROWN PILSENER.

(THE UNITED BREWERIES, LIMITED, COPENHAGEN; LONDON OFFICES, 46, QUEEN VICTORIA-STREET, LONDON, E.C.)

The special feature of these beers is the remarkably low alcoholic strength while the amount of malt nutritives is high. The analysis of Crown beer thus gave the following results: malt extractives, 8.77 per cent.; mineral matter, 0.13 per cent.; and alcohol, by weight 1.25 per cent., by volume 1.57 per cent., equal to proof spirit 2.75 per cent. The beer possesses a strong malty flavour and is only slightly effervescent. In spite of the small amount of alcohol which it contains we could find no added preservatives. The alcoholic strength only slightly exceeds that of many so-called temperance drinks, as, for example, ginger-beer. The Pilsener beer gave the following results on analysis:

malt extractives, 6.49 per cent.; mineral matter, 0.10 per cent.; and alcohol, by weight 1.75 per cent., by volume 2.20 per cent., equal to proof spirit 3.85 per cent. This is a light beer with delicate bitter flavour, and free from excess of carbonic acid gas. It was free from the usual beer preservatives. Both beers are satisfactory in composition, pure, and wholesome, containing a minimum of alcohol and a maximum of the nourishing extractives of malt.

(1) ANTISEPTIC PLASMA; AND (2) GLYCERO-PHOSPHATES.

(THE ANGLO-AMERICAN AND CONTINENTAL PHARMACEUTICAL COMPANY, LONDON, PARIS, AND NEW YORK. LONDON OFFICE: 39A, TAMWORTH-ROAD, CROYDON.)

This antiseptic plasma is a brownish, sticky substance containing well-known antiseptics. An important feature in regard to its composition is the fact that it is made up with absorbent infusorial earth (kieselguhr and kaolin) instead of the primitive clay. The plasma dressing possesses an odour of oil of wintergreen, and we found indications of boric acid. The powerful antiseptics salol and thymol are also present. The dressing presents very desirable properties, non-irritating, absorbent, and hygroscopic. The syrup of the acid glycerophosphates (Huxley) is a clear brown fluid without deposit and keeps well. The value of such a compound acid syrup is now well recognised. The preparation is contained in a ruby glass bottle, so that light may have no deteriorating effect upon it. The preparation is agreeable to take and contains the various salts of glycerophosphic acid in approved ratio and amounts.

VARIOUS COCOAS.

(ADOLPHE SANDERS, 29, FENCHURCH-STREET, LONDON, E.C.)

Several grades of cocoas have been submitted to us from the above agency which are said to represent the best qualities of manufactured Dutch cocoas. Each and all have been so prepared as to render the cocoa more "soluble" and more easily digestible. Thus the indigestible fat has been reduced to a minimum and the cocoa ground to a finely comminuted powder which gives no sediment in the cup. Two specimens we examined were from the well-known firm of Bensch and Co., both proving of excellent quality, yielding a hot-water infusion of excellent flavour. The one marked "Supra" was a shade superior to that marked "Amstel." These samples are supplied by the above agent in wholesale quantities—that is, in barrels of two hundredweight each. The third sample we examined was manufactured by Messrs. Betke and Co., also a Dutch firm. This cocoa is supplied by the above agent in tins. It is of excellent character, with a pleasing aroma characteristic of high quality. The cocoas all gave evidence of treatment with a small quantity of alkaline salt—a recourse which is not objectionable, for it adds nothing injurious while it renders the cocoa more easily suspended in hot water, or "soluble" as it is wrongly called, and more digestible. Microscopical and chemical examination were alike satisfactory.

## New Inventions.

### IMPROVED DRESSING WAGON.

MESSRS. ARNOLD AND SONS have just completed a very serviceable and useful dressing wagon for the surgical out-patient department of the Dumfries and Galloway Royal Infirmary. This dressing wagon is specially designed for use in a surgical out-patient room, but is equally well adapted for use in a ward or private surgery; indeed, for the latter it is especially well adapted. It consists of an upper air-tight case for antiseptic dressings. The front of this case folds down and, being supported by chains on either side, forms when open a convenient tray for cutting dressings

upon. The floor of the case is occupied by three drawers intended for carbolic macintoshes, coats, and towels. There are four large compartments for various antiseptic absorbent wools, and two smaller compartments for lint, gutta-percha tissue, &c. There are also five drawers, four being intended for bandages of various sizes. The fifth is divided into compartments for cylindrical rolls of gauze. Each compartment is made air-tight by a lid which has a narrow slit over the centre of each compartment through

which the gauze can be drawn and cut off to the required length. The lid is so arranged that it forms a tray upon which the cut ends of the gauze lie and they do not therefore form a hindrance to the easy running of the drawer. There is also a covered compartment in this drawer for catgut, horsehair, needles, &c. The whole is surmounted by a glass top upon which lotion-bottles, &c., stand, and below there are two glass shelves for lotion basins, instrument trays, &c.

Dumfries.

GEORGE R. LIVINGSTON, M.B. Edin.

### MARTINDALE'S (1) UREA APPARATUS; AND (2) BACTERIOLOGICAL FORCEPS.

FROM time to time a great many forms of apparatus have been devised for the ready estimate of urea in urine all depending upon the fact that hypobromite of soda breaks up urea into nitrogen and carbonic acid. The latter gas is absorbed by the excess of soda and the former is collected and its volume noted. The method is only approximately accurate, but it is sufficiently so for clinical purposes. Mr. Martindale (10, New Cavendish-street, W.) relies upon the measurement of water displaced by the nitrogen evolved. For this purpose he employs a generating bottle in which a measured quantity of urine (2 cubic centimetres) is discharged into 10 cubic centimetres of hypobromite by means of a pipette fitting into a tight rubber cork. The cork is fitted with an outlet (glass) tube connected with a bottle filled with water and placed at right angles with, and a few inches above, the generating bottle. The gas evolved in the generator displaces an equal volume of water which descends through a glass tube fitted into a cork into a measure glass. The principle, though simple enough, introduces more pieces of apparatus than in methods in which the nitrogen evolved is directly measured, as in the Doremus tube, and we are not sure that any greater accuracy is thereby gained. All bacteriologists working at the bench will appreciate Mr. Martindale's bacteriological forceps, which are designed to prevent stain or other reagent from drying and running off the cover-slip by capillary action. One limb of the forceps has attached to it a square (or round as the case may be) disc of metal to receive the cover-slip which is kept in position by the pressure of the other limb shaped like a bent end of forceps. These forceps also obviate the need to continually dry the limbs of the instrument during the process of staining or washing.

LONDON: SATURDAY, NOVEMBER 16, 1901.

## The Annual Meeting of the Royal College of Surgeons of England.

ON Thursday, Nov. 21st, the Council of the Royal College of Surgeons of England will render to the assembled Fellows and Members an account of their stewardship for the past academical year. All the work that the Council has done has been done well, and we may cordially express our thorough approval of their management as recorded in their report. It is not, however, with what they have done that we are now concerned, it is rather with what they have left undone. They have made no attempt to give representation on the Council to the Members of the College. Ever since these annual meetings of Fellows and Members were established some 17 years ago resolutions have been carried time after time to the effect that it is desirable to extend the franchise to the Members, yet the Council has done nothing. On one occasion, it is true, they took the opinion of the Fellows on the subject; yet, since only one half of the Fellows replied to the circular from the Council, the adverse opinion then expressed cannot be seriously taken as representative of the real wish of the holders of the Fellowship. Moreover, five years have elapsed since that vote was taken; surely, then, it is fully time to endeavour to ascertain once more what the Fellows think on this most important subject. For important it, indeed, is. The rights of nearly 20,000 Members are absolutely ignored: in no way are they represented on the Council. No references to the Charter, no appeal to the desirability of representation on the Council being confined to the more highly-educated Fellow, can be of any avail in this discussion. It is of the Charter itself that we complain, for it excludes from the government of the College those who form nine-tenths of the body corporate. The Members from their very position as Members must form part of the College, and therefore should be directly represented on the Council. They are not merely Licentiates, they are Members of the Royal College of Surgeons of England. Nearly 60 years have passed since the injustice inflicted by the Charter of 1843 first arose, and ever since that year the Members have striven, sometimes in one way and sometimes in another, to obtain redress for the ills of which they complain, but hitherto in vain. The annual meeting is the only occasion when they can publicly bring forward their claims and these just claims cannot be for ever ignored. A motion urging the importance of this extension of the franchise forms the first agenda at the approaching meeting. It invites the Council to suggest any way in which the Members of the College may be represented on the Council. This motion is to be brought forward by Dr. THOMAS MORTON, and all who have heard him speak at previous annual meetings of the

College know that all he says will be said justly and moderately. But some other speakers at this meeting are prone to forget that argument is the most likely means of convincing the Council. We would therefore urge on the Members the importance of moderation in the manner in which they speak at the annual meeting. The time has gone by for violent declamation and perfervid oratory: it cannot advance the cause of Members and it may tend to retard it. Many of the Fellows are keenly in favour of the just claims of the Members and would do much to support them. The Council itself is also changing. As the years go by the *personnel* of the Council alters; the older, more conservative members of that body retire therefrom and are replaced by younger men, more alive to the needs of the times; indeed, we have reason to know that a large proportion of the Council itself is willing, if not anxious, to support any reasonable scheme of representation of the Members. The present time is exceedingly suitable for bringing forward the matter, for we are on the eve of an election of Direct Representatives on the General Medical Council. Nearly everyone agrees that the present number of Direct Representatives is too small. Were, however, the representative of the Royal College of Surgeons of England on that Council elected by the Members he would represent many thousand medical men, so that, in fact, he would be equivalent to a fourth Direct Representative. Mr. BRINDLEY JAMES is bringing forward a motion suggesting that the Representative of the College on the General Medical Council should be chosen by the Fellows and Members of the College of over 10 years' standing. We must confess that we fail to see the object of thus limiting the Members who might vote on this matter, but perhaps the mover of this motion considers that it is more likely to be acceptable to the Council if the voting power is confined to the senior Members.

We have so often on previous occasions supported the claims of the Members that it would be superfluous to recapitulate all that may be said in their favour. We may, however, mention that until the Council of the College has on it those who are the representatives of the general practitioners the Council will fail to appreciate the importance of many questions which have a vital interest for those in general practice. It is impossible, or well-nigh impossible, for a surgeon who has always practised as a consultant to appreciate the daily difficulties and the daily trials of the general practitioner. Nowadays, with the intense competition which exists both from medical aid associations and from prescribing druggists, the struggle for existence is very keen, and much assistance might be vouchsafed to medical men by the timely succour of the Council of the College. The voice of so august a body is heard respectfully even by those in high authority, and were the Council earnestly to take in hand the subject of medical reform we might hope to see progress in medical legislation such as has never been seen before.

## Scarlet Fever and Milk.

THE London County Council have just issued a report by their medical officer which presents several points of considerable interest upon which we propose to comment. The report

deals with an outbreak of scarlet fever in London during May of the present year, which occurred for the most part in Shoreditch and Bethnal Green, other districts—e.g., Finsbury, St. Pancras, and Islington—being in a less degree involved. An increase in the number of cases of scarlet fever notified was first observed in Shoreditch by Dr. L. T. F. BRYETT who, on May 1st, informed Mr. SHIRLEY MURPHY of the fact, and also that he had found that the persons affected had derived their milk-supply from two local vendors, one in Shoreditch and the other in Bethnal Green, the adjoining district. He had also ascertained from Dr. G. P. BATE that there was a simultaneous increase in the number of cases of scarlet fever in Bethnal Green which had been supplied with milk from the vendor in that district, and that while the Shoreditch vendor had derived his supplies from two middlemen the Bethnal Green vendor had received his supply from one of the two. Obviously the supplies of the middleman who had sent milk to both these vendors was under suspicion. At this point the administration of the London County Council took up the inquiry while the medical officers of health of the districts involved continued to trace the source of the milk-supply of every person attacked with scarlet fever and placed this information at the disposal of the Council's medical officer.

The middleman whose milk thus came under suspicion furnished a list of over 40 farms from which he received his milk. Dr. W. H. HAMER prosecuted inquiries among the local vendors who it was ascertained had supplied milk to the infected persons, and every effort was made to learn from the middleman's van-men from which farms they had received their milk. Further letters were sent to the medical officers of health of the areas in which the farms were situated from which milk came to the middleman, and on May 3rd the evidence had so far accumulated that two farms in Staffordshire had come especially under suspicion. Dr. HAMER, therefore, on May 4th proceeded to Staffordshire and while there Mr. SHIRLEY MURPHY was able to telegraph to him that he had received information of the occurrence of illness resembling scarlet fever in the family of one of these farmers, a suspicion which was later confirmed. Mr. SHIRLEY MURPHY had moreover, on the morning of May 4th, informed the middleman that the supply of milk from this farm should be stopped. Thus in 72 hours a complex problem had been practically solved by methods much resembling those of Mr. SHERLOCK HOLMES, and all that remained was to study the results of the stoppage of milk from the infected source. The report before us gives full information of the summary arrest of the development of scarlet fever in the districts involved and of the evidence which showed that a correct conclusion had been arrived at as to the original source of the mischief. The report also contains matter of much practical interest in connexion with the distribution of an infected milk-supply in London. The most important point which is brought out is that the middleman had no records which would enable him to give information as to how the milk from his several farms had been distributed among the local vendors. Hence the memory of his van-men had to be relied upon and this does not appear to have been invariably trustworthy. The consumers, of course, had no knowledge as to the sources of supply, the local vendors generally were satisfied with knowledge which was practically not more

precise, and the middleman himself had no exact knowledge as to how the milk from his various sources was distributed. Hence, when the milk of a particular farm acquired infective properties there were no means of ascertaining which farm it was that was involved, and while the evidence was being analysed infective milk was being distributed, and as a result some 300 persons were attacked with scarlet fever. Clearly this is a possibility which ought to be prevented in the future, even if it causes some inconvenience to the milk trade. It ought to be possible for each local vendor to know from what source his supply is derived so that that supply can be eliminated if it is found to be causing disease among the consumers. The fact that the farm from which the infective milk was received was detected so early in the outbreak with which this report deals may, of course, be used as an argument on the other side, but it cannot always be depended upon that future inquiries will be conducted as expeditiously as they were in the case which we are discussing; and even the May outbreak would probably have ceased a day or two earlier had it been possible—as it ought to have been if the information had been available—to stop the supply of the infective milk at an earlier period.

There are other points in which the London Public Health Act requires amendment. It is, for example, patently absurd that it should not be contrary to law to supply a particular milk in other districts when its supply has been stopped in one district. Some better machinery for excluding infective milk from London is obviously needed, and this, it may be hoped, will at no distant date be provided. An interesting diagram in the report shows the sex- and age-distribution of the persons attacked during this outbreak. Males and females were attacked much as they are at ordinary times, but persons aged from 15 years and upwards were in this outbreak attacked in undue proportion, suggesting that when infection is received in a food-supply many persons suffer who in the ordinary course of life escape. This is not matter for surprise.

### The Medical Profession and the Public Vaccinator.

WE have thought it right to give a hearing several times during the recent recrudescence of small-pox in London to communications upon the subject of the relations which should exist between the medical profession and the public vaccinator. Undoubtedly there has been a growing feeling on the part of the general practitioners of the country that the public vaccinators have made a zealous discharge of their official duties resemble to a disagreeable degree the process of poaching upon the patients of their professional brethren. If no one has said quite so much as this, the feeling that is thus described has been present in the minds of our correspondents. This week we publish two letters on the subject which are only specimens of many that have reached us, and which bring the matter up for discussion in a convenient form because they formulate a distinct charge against the public vaccinators as a body. The charge is that a proclamation issued by the organising secretary of the Association of Public Vaccinators for

England and Wales to the public through the medium of the press is unprofessional in character.

The following is the proclamation in question :—

In view of the fact that considerable misapprehension exists in regard to revaccination, the organising secretary of the Association of Public Vaccinators for England and Wales writes to inform the public :—

1. That every person in England and Wales is entitled to demand revaccination at his own house, free of charge, at the hands of the public vaccinator of his district, provided that such person has not been vaccinated or revaccinated within 10 years preceding the date of his demand.

2. That the name and address of the public vaccinators for each district in England and Wales can be obtained from the clerk to the guardians and from the registrars of births and deaths.

3. That public vaccinators are the only medical men who are compelled to use the safeguards prescribed by the regulations of the Local Government Board, and that they are the only persons who can obtain the pure glycerinated calf lymph prepared in the laboratories of the Local Government Board, and that they are compelled to use that lymph in all cases of vaccination and revaccination in their own district.

It is with regard to the third clause of this proclamation that we have received indignant letters of protest. A large number of our readers consider that it amounts to a thinly-disguised attempt on the part of the public vaccinators to detach patients from their professional brethren. The assertion that the public vaccinators are the only medical men who are compelled to use the safeguards prescribed by the regulations of the Local Government Board almost amounts, in their opinion—and we see very clearly their side of the matter—to the insinuation that the general practitioners of the country are not able to take proper precautions to secure safe and efficient vaccination. Similarly, the statement that the public vaccinators are the only persons who can obtain the pure glycerinated calf lymph prepared in the laboratories of the Local Government Board throws a doubt by implication upon the quality of the lymph used by operators not holding an official appointment. The circular, in short, while pointing out to the public the ease with which the public vaccinators can vaccinate all persons resident within their district, makes claim for them that they are the only persons who can perform the little operation satisfactorily, being the only persons who possess the proper lymph with which to make inoculations. If these claims are not made in set terms it is certain that these are the only deductions that the public is likely to draw after reading the circular. And everyone knows that these deductions are entirely false. It is true that the public vaccinators are the only persons who can obtain the Local Government Board lymph, but the Local Government Board lymph is not the only efficacious lymph that can be obtained. It is obviously absurd to suppose that vaccine lymph can only be properly prepared in a laboratory rented by the Local Government Board and by a bacteriologist employed by the same body. Indeed, we have shown that this is not the case. THE LANCET Special Commission on Glycerinated Calf Vaccine Lymphs reported last year<sup>1</sup> upon the quality of thirteen lymphs then on the market, when the Local Government Board lymph was found to occupy a middle place. It was freer from extraneous matter than were six brands, but it did not answer quite so favourably to tests as six other brands did—all, however, were found to be absolutely pure of pathogenic organisms.

That is to say, that, unless the Local Government Board lymph has improved during the last eighteen months more than the other brands of lymph have improved, the monopoly enjoyed by the public vaccinators in the acquisition of the lymph gives them, as we should expect, no particular advantage.

The Association of Public Vaccinators for England and Wales must qualify or withdraw their notice to the public if they desire to receive the support of their professional brethren. We are not blind to the difficulties with which public vaccinators have to contend. Their posts are not enviable ones: they are not well paid, and, in certain districts, they are not worth having. The public vaccinators and vaccination officers form the executive of the Government upon whom, to a certain extent, the responsibility of seeing that their districts are kept properly vaccinated devolves. The vaccination officers are right to issue instructions to the public urging upon the public the necessity of being vaccinated and pointing out the way in which this result can be secured. But such notices should not be carelessly worded. We have grave doubts whether the proclamation in question will be countenanced by many public vaccinators who are themselves in medical practice and realise to the full the importance of adhering strictly to medical etiquette in all dealings with their colleagues, while they must see that the emoluments and considerations that they enjoy as Government officials are due to the fact that they are medical men. Anything which tends to persuade patients who are perfectly well able to pay for the small operation of vaccination to present themselves at the offices of the public vaccinator so as to have the operation performed gratuitously is to be regretted. The medical profession does too much work for no pecuniary return, while the public has in many directions shown itself to be without conscience in obtaining medical service gratis wherever it can be secured. The fact that it is open to any man, whatever his status or occupation, to be vaccinated for nothing by the public vaccinator is not one that requires to be brought home to the mass of the public at all. They may be trusted to find out such things for themselves. This, however, is not the more serious side of the circular. The serious side is the insinuation that the public vaccinators possess qualifications and opportunities for performing an efficacious operation which are not possessed by their professional brethren, the general practitioners. This false suggestion may not have been intentional. We will go further and say we are sure that it was not intentional, but it is there. No one can read the circular without seeing that it is there, and many hundreds of general practitioners have read the circular and have been disgusted with it because of the slur upon them which they cannot help reading into its words. The matter is now so serious that we think another circular should appear correcting the impressions of the first one, and stating in the clearest possible terms that there is no reason whatever to suppose that the public vaccinators can vaccinate the public better than can other medical men. The public vaccinators will treble the difficulty of their already difficult position if they divorce from themselves the sympathy of their medical colleagues, especially in districts where the public is not too well

<sup>1</sup> THE LANCET, April 28th, 1900, p. 1227.

inclined towards them. From motives of sheer policy, if not of right feeling, the offending third clause of the circular of the organising secretary of the Association of Public Vaccinators for England and Wales should at once be recast or, better still, withdrawn.

## Annotations.

"Ne quid nimis."

### THE ARBITRATION IN THE POTTERY TRADE.

LORD JAMES OF HEREFORD, the umpire in this case, has brought the proceedings to an abrupt termination by declaring that as it was shown that lead-poisoning had greatly decreased under the last rules there was no need to impose fresh ones, at all events for the present, as to the use of fritted lead or as to the examination of adults. These questions, he added, might be postponed for 18 months, and would be then again postponed if necessary. Was ever such a ridiculous situation created in the teeth of the laborious inquiries and reports undertaken by the Government's chosen experts, Dr. T. Oliver and Dr. T. E. Thorpe, in which the one clear recommendation standing out before all others was the adoption of definitely fritted lead. We learn that this decision has given general satisfaction locally—that is, in the pottery district at Hanley. We wonder whether this satisfaction is shared equally by the workers and their masters. We view the decision with the deepest dismay; it is premature and dangerous.

### PNEUMOTHORAX FROM PARACENTESIS THORACIS.

PNEUMOTHORAX is a rare result of paracentesis thoracis. At the meeting of the Société Médicale des Hôpitaux of Paris on Oct. 11th Dr. Variot and M. Pierre Roy related the following case. A girl, aged 11 years, was admitted to the Hôpital des Enfants-Malades on May 29th. She was said to have had pneumonia in March and a relapse in April. After this she had a cough and pain in the side, expectorated some mucus, and lost about five pounds. Over the lower two-thirds of the right lung behind vocal fremitus was absent, dullness was well marked, and the vesicular murmur was almost abolished. At the level of the spine of the scapula slight bronchial breathing was heard. The apex of the lung was normally resonant. The temperature was normal. There was evidently a slight pleural effusion, probably serous. Counter-irritation and the administration of squills proved useless. On June 17th two exploratory punctures with a Pravaz syringe were made in the seventh and eighth intercostal spaces without result. Nevertheless paracentesis was performed. The patient was placed in the dorsal decubitus position and the fine needle of Potain's instrument was inserted in the seventh intercostal space in the axillary line. Serous fluid flowed slowly into the bottle and was mixed from the first with air bubbles. It was certain that no air was entering by any of the tubes. The liquid flowed so slowly that in three or four minutes only 120 grammes were discharged. The child was then seized with persistent cough, and the needle was rapidly withdrawn and the opening was closed with collodion. There was no trace of blood at any time in the fluid. After the needle was withdrawn the coughing instead of stopping increased. Soon the child expelled by the mouth and nose a large quantity of sanguineous serous fluid which was a little frothy. At the same time the face became cyanosed and the pulse thready. Instant asphyxia was feared. The child complained of acute pain in the right side

and cried out that she was being stifled. Under subcutaneous injection of ether, inhalation of oxygen, and a sinapism applied to the back the symptoms diminished. The expectoration, however, continued, and in a quarter of an hour the child had expelled 250 grammes of frothy sanguineous liquid. On auscultating the chest behind, over the position formerly occupied by the effusion, amphoric breathing was heard and the cough had an amphoric character. The percussion note here was tympanitic. A quarter of an hour after the paracentesis the child was quiet. Half an hour later fits of coughing reappeared with the same sero-sanguineous expectoration. They were assuaged by the sucking of ice and a hypodermic injection of morphine (one-seventh of a grain). In the evening she was comfortable, but the temperature was 104° F., and every time she moved she coughed; in the afternoon she had expelled about 250 grammes of the fluid. On June 18th the temperature was normal; about 190 grammes of the fluid were expelled. On June 19th the cough had disappeared. In the right infrascapular region amphoric breathing persisted, but in the upper part vesicular breathing was heard. Percussion seemed to show a small quantity of fluid in the pleural cavity, but a succussion sound could not be obtained. On the following days large mucous rales were heard in front on the right side and there was slightly fetid muco-purulent expectoration with factor of the breath. On July 10th amphoric breathing was heard with difficulty. She was sent to a convalescent home. On August 26th sonorous rales were heard in both lungs. There was dullness of the lower two-thirds of the right chest with slight diminution of the vesicular murmur. On Sept. 4th there was some dullness of the lower third, and inspiration here was harsh and expiration slightly bronchial. In this case partial pneumothorax was evidently produced by the paracentesis. Dr. Variot and M. Roy insisted that the lung was not punctured by the needle, for not a drop of blood escaped with the aspirated fluid. The fact that 120 grammes of fluid were removed shows that the external air was not admitted to the pleural cavity. They think that in the region of the pleurisy the lung tissue was diseased and fragile and was torn under the influence of the aspiration, perhaps by the strain on a pleural adhesion. The expectoration was evidently due to the passage of the pleural effusion through the pleuro-pulmonary fistula so formed.

### THE COAL SMOKE ABATEMENT SOCIETY.

As we announced last week, a public meeting will be held in support of the objects of this society at Grosvenor House on Wednesday next, Nov. 20th. The following motions will be submitted to the meeting:—

1. That the pollution of the air by coal smoke is an evil injurious to public health and that every effort should be made to secure the laws existing for its prevention being kept in effective operation.
2. That the rapid deterioration of works of art and vegetation in London due to the effects of coal smoke demands an immediate and comprehensive remedy.
3. That the darkness and impurity caused by smoke pollution have a directly demoralising effect upon the inhabitants of a great city.
4. That as a matter of private and public economy the escape of smoke from coal fires is a preventable waste of energy and material.
5. That this meeting, in recognising the practical results already achieved by the Coal Smoke Abatement Society with the limited resources at its disposal, and in approving its line of action, pledges itself to use its best endeavours to place it in a position to extend its operations.

We are not sure how far pollution of the atmosphere by coal smoke has played a determining part in the dense fog that enshrouded London during the first week of November. Probably no two experts would give exactly the same opinion as to the influence that it played, but certainly no one can doubt that its share was considerable. An acute remembrance of the miseries of that week should be present in the minds of all those who attend the public meeting, which we trust will be a large one, and should impel them not only to pass the motions with acclaim but to work with the Coal Smoke Abatement Society in finding

a remedy for them. The excellent society, over which Sir William Richmond presides, is a remarkably alert and active one. It has received but small support either from the public or the medical profession and deserves much wider notice and much more generous help. Medical men have many ways, perhaps more strictly medical in their direction, of getting rid of their spare guineas, but this society is one that would appeal with particular force to the lay mind if the therapeutic nature of its work were understood. We wish all our London readers would impress upon their patients the fact that to abate coal smoke in the metropolis is to improve the public health of the city in a marked manner.

#### THE PHYSIOLOGY OF MARCHING.

"The Physiology of Marching" is the title of an essay by Herr N. Zuntz and Herr Schumburg recently published in Berlin by Hirschwald and abstracted in the *Centralblatt für die Medicinischen Wissenschaften* for October. Their investigations, which have been carried on for some years, were undertaken to ascertain the limits of weight that a soldier on the march could advantageously carry. They experimented on five healthy students who had already seen service and who for a long period marched fully equipped about 15½ miles daily. Amongst the more important points noted were that sphygmograms taken before, during, and after the march showed that the increased work of the heart consequent upon the muscular exertion prolonged the systole of the heart and the ascending line of the pulse curve at the cost of the diastole—an effect that was distinctly visible after a march of only 12 miles. This prolongation of the systole rose with the amount of weight carried to such a degree that when the beats of the heart were between 140 and 150 per minute the duration of the systole was to that of the diastole as 1 is to 1. So that the period of the rest of the heart became constantly less, indicating a not inconsiderable degree of increase in the work of the heart. An increase of the regulation weight carried by German soldiers from the ordinary amount of 48·4 pounds to 59·4 pounds produced the same effect, whilst when the weight was raised to 78·4 pounds the danger of seriously injuring the heart was greatly increased as shown by a fall of the blood-pressure and of the arterial tension. Simultaneously an acute dilatation of the heart, recognisable by percussion, and enlargement of the liver in consequence of blood stasis and accumulation of blood in that organ were observable. As a result of the dyspnoea from exertion the driving force of the heart became still further reduced, the volume of blood propelled into the arteries was diminished, and the blood in the great veins re-entered the heart in smaller quantity and more slowly. In healthy persons the dilatation of the heart gradually disappears and in the course of two or three hours the normal conditions are restored. Speaking generally the number of red corpuscles and the specific gravity of the blood increased during the march owing to the great loss of fluid by the lungs and skin. The frequency of the respirations was increased whilst marching, though after a short rest the number returned to the normal. The vital capacity was diminished. The heat of the body increased on the march, sometimes to quite a remarkable extent and even though the weight increased and there was more or less physical exhaustion. In one case it amounted to 40° C. (104° F.) and more. In order to determine the consumption of food and the nature and quantity of the excreta the diet was kept as uniform as possible. It appeared, to the great surprise of the experimenters, that notwithstanding the abundant secretion of sweat the urine on marching days was more abundant and of less specific gravity than on the days when rest was taken. Albumin, indicated by a precipitate on boiling, was rarely

present and then only for a brief period. The nitrogen-containing substances were just the same on the days of rest and of marching, so that there was no increase of metabolism in the albumin of the body, nor was the composition of the contents of the intestine materially different on days of work and days of rest. Subsequent sections of the essay deal with the exchange of gases during work and while at rest, as well as the heat value of the work done. 70 per cent. of the heat generated is carried off by the sweat and the greater the amount of heat produced by work the more abundant is the secretion of sweat, but many factors have to be considered, as the temperature and degree of moisture of the air, the velocity of the wind, and exposure to the sun. As the men became more "trained" by exercise the amount of sweat diminished.

#### THE HOSPITALS AT ATHENS.

In the *Phonographic Record* for October Dr. G. F. Atchley (consulting surgeon to the Bristol General Hospital) gives an interesting account of a visit he recently made to the hospitals at Athens. The children's hospital, about two and a half miles outside the city, "consists of one large ward containing 16 to 18 beds with a small isolation ward and nurses' rooms. The original design contemplated six of these pavilions, but, as usual, want of funds has hitherto prevented further building. The situation is perfect; abundance of room for any possible extension or for playgrounds. The building has been 'scamped,' the tiled floors are all going to pieces, the windows do not fit, and generally the work has been done in a very inferior manner. I understand that more care will be taken in future to secure better work. A large number of patients were in bed with various forms of tubercle, especially tubercular peritonitis. The nurses were all English. It is found very difficult to get Greek nurses to stay; they all want to be nearer Athens. .... At present any cases which require operation are sent to the Evangelismos Hospital, where the facilities for operating are almost perfect. The Evangelismos is a large general hospital for over 200 patients and having both medical and surgical sides. Here I found everything in the highest state of efficiency. The practical part of medicine and surgery was up to date and in some respects even in advance of our best English hospitals." Dr. Atchley saw Dr. Tsakonas operate on a boy with stone and on a woman with ovarian tumour. "The operation chosen for the calculus was suprapubic. It was most successfully carried out, the wound in the bladder being stitched with catgut (continuous suture) and the outer wound being treated in the same manner." For the removal of the ovarian tumour "a new method of anaesthesia was used. .... A needle, made especially for the purpose and like a long hypodermic needle, was connected with a syringe and inserted opposite the second lumbar vertebra just outside the backbone. It was made to penetrate the spinal canal and only a little cerebro-spinal fluid escaped. Then cocaine was injected. In about 20 minutes anaesthesia was produced over the whole lower half of the body below the umbilicus. Although in this instance not quite enough cocaine had been used and a little chloroform became necessary, Dr. Tsakonas told me that he had used it in 163 cases without a single accident. Usually the anaesthesia is complete. The patient remains perfectly conscious all the time of the operation and there are positively no after-symptoms whatever. The practical difficulty seems to be to ascertain exactly the amount of cocaine which should be allowed to enter into the spinal canal. Probably eucaine or one of the similar compounds would be less likely to be injurious should an overdose be injected. It has now become a customary practice in this hospital and

further experience will doubtless be attended with increased accuracy as to the dose as well as the method of introduction. The two tumours were removed with great skill and the sutures used were again continuous. First, the peritoneum was hemmed, then the musculo-fibrous covering, and, lastly, the skin, all with one thread. A single large suture tied the skin and fascia together in the middle of the wound. Collodion was painted over all, an antiseptic dressing applied, and a bandage completed the proceeding. It seems that here all these wounds heal up by first intention and are never followed by secondary trouble. The greatest precautions are taken against the introduction of germs. On entering the theatre I was, in common with all those present (about 20 in number), covered with a sterilised waterproof cloak and sleeves; the air had been also sterilised and, of course, all instruments. No sponges are used, but sterilised pieces of calico like small pocket-handkerchiefs, and each of these when used was clipped by the catch-forceps. I subsequently went over the whole hospital under the guidance of one of the resident surgeons and was delighted and somewhat surprised at its very advanced and scientific management. .... Greek nurses are here to be found and from what I saw were very well trained." Dr. Atchley also visited the military hospital, nursed by English nurses. This he found to be very efficient but not so up-to-date as the one just described.

#### HOMO VERMIGENES.

THE *Daily Express* of Nov. 4th publishes the kind of *ad captandum* illustration that appeals to the great mass of newspaper readers still in the habit of regarding science, and especially the Darwinian theory, in the light of unpleasant paradox. The picture in question represents the "ladder of evolution," and this, with accompanying letter-press, is headed "How a Flat Worm became a Man." Professor Ernst Haeckel of Jena is thus pictorially represented as tracing the descent of man from the flat worm through the eel, the iguana, and, *longo intervallo*, the opossum, the stenops, and such apes as the gibbon and the semnopithecus. From the point of view of embryology this theory is, of course, ancient, for as long ago as 1704 we find Geoffroy, a learned Parisian doctor and member of our own Royal Society, maintaining a thesis which, at first sight, seems a distinct adumbration of Haeckel's view. The French title of the thesis, as translated by Nicolas Andry from the Latin, is "*Si l'Homme tire son Origine d'un Ver?*" Geoffroy seems to have been familiar with the microscopical investigations of Leuwenhoeck, published some 20 years earlier, and though he does not actually refer to the Dutch histologist's "animalcule" in human semen, yet his "worm" is practically the same thing. The spermatozoon does not seem to have been detected till a much later period, yet Geoffroy had certainly got in a fanciful way to the root of the matter. Man, he maintains, springs from a minute worm, which, issuing from the male, unites with the ovum of the female, thus originating the human embryo. Throughout his treatise he insists that the processes of fertilisation, gestation, &c., are the same throughout the animal world. Man, according to him, reproduces exactly as do other viviparous animals. Indeed, his views come so near what would in his day have been considered grave heterodoxy that he must certainly rank as an important pioneer of the modern doctrine of evolution.

#### PRECOCIOUS MATERNITY.

IN the October number of the *Maryland Medical Journal* Dr. L. M. Allen, Associate Professor of Obstetrics in the University of Maryland, describes a case in a coloured girl,

aged 11 years, who was when in the seventh month of pregnancy admitted into the Free Lying-in Hospital of the university. She had the appearance and characteristics of a child of 11 years, was fond of playing with dolls and of childish amusements, and was four feet five inches in height; there was no evidence of rickets or any other disease. Menstruation first began, as far as could be ascertained, at the age of 10 years and three months, and had been regular. The pelvic measurements were as follows in centimetres: interspinous, 22; intercrystal, 21.5; right external oblique, 18.5; left external oblique, 18.5; external conjugate, 14.25; circumference, 77; distance between trochanters, 28.25; diagonal conjugate, 8.5; and conjugata vera, 6.5. The foetal heart was heard with maximum intensity in the left lower uterine quadrant. The pregnancy advanced to full term and labour began at the expected time. After the labour had lasted about 14 hours the patient was put upon the examining table, and while the resident physician was preparing to make an examination the child was born. After half an hour the placenta was delivered artificially. A normal amount of blood was lost. The patient made a rapid and uneventful recovery. The infant was well developed in every respect, and when sent away to an orphan asylum on the sixteenth day was in very good condition. It weighed seven pounds two ounces. The measurements of the head were as follows in centimetres: occipito-mental, 12.6; occipito-frontal, 11.2; suboccipito-bregmatic, 10; biparietal, 8; bitemporal, 7.2; circumference of head, 32. Points of interest in the case were the extremely easy labour with a very small pelvis and the comparative absence of pain. During the whole labour hardly a sound was uttered by the patient, even during the passage of the head and shoulders over the perineum. At the time of conception the mother was about 10 years and 11 months old, and when the child was born her age was 11 years and eight months.

#### THE WHEAT PROBLEM.

AN investigation of great interest, which is likely to render valuable service to those engaged in the management of crops, has been undertaken by Bernard Dyer, D.Sc., F.I.C., the results having recently been published in the *Philosophical Transactions of the Royal Society*. Some years ago Dr. Dyer communicated an interesting paper to the Chemical Society in which he proposed the use of a 1 per cent. solution of citric acid as a means of approximately differentiating by the application of chemical analysis between the total and the probably available phosphoric acid and potash in soils. The citric acid method was the result of an attempt to imitate in the solvent used the acidity of root sap based on a preliminary examination of the root acidity of 100 specimens of flowering plants representing some 20 natural orders. There is no doubt that this method has brought valuable results to light. It has been applied to 22 samples of soil drawn from various plots on which barley under very various manurial conditions had been continuously grown for over 40 years. The results were of sufficient interest to lead to the undertaking of a similar but much more extended examination of the soils of Rothamsted in what is known as the Broadbalk field. These plots have been continuously under wheat now for considerably more than 50 years. The manurial history of each plot and its yearly yield of grain and straw are all on record and periodical analyses of the ashes of each year's crop from most of the plots have been completed sufficiently to allow of an estimate of the yearly removal of both phosphoric acid and potash. The soil of each plot was sampled in 1865 and in 1881, as well as in 1893, the three sets of samples, representing not only the surface soil (the first nine inches) but also the second and third depths, each again to the extent of nine inches. These samples were placed by the late Sir John

Bennet Lawes and Sir Henry Gilbert at the disposal of Dr. Dyer for the determination of the total phosphoric acid and of the potash soluble in strong mineral acid, but more particularly for the further investigation of the citric acid process which was calculated to give a better insight into the fertilising value of various soils at various periods of their history and at various depths. The results are, of course, of scientific interest, but they are of practical value also as throwing a light upon one of the most important questions to the community—namely, the successful raising of food upon the land. When examined by this citric acid method certain of the soils showed differences which can be traced to variations in manurial treatment more than 40 years previously. In regard to phosphoric acid it is shown that by far the greater portion of the unconsumed phosphoric acid added in manure is accumulated in the surface soil, although most of the phosphoric acid had been originally soluble in water and its application had extended over 50 years. In the case of dung, however, there is a considerable descent into the second and third (nine-inch) layers. In the case of superphosphate there is evidence of a descent into the second, and even the third, nine-inch layers. In chemically manured plots the greater part of the calculated accumulation of phosphoric acid is found by analysis in the surface soil, and a large proportion of it proves to be soluble in weak citric acid. The citric acid method thus enables an evaluation of the soil to be made at different depths, which is of the greatest importance in connexion with the problems of root-range and subsoil feeding. The results obtained by the use of weak citric acid in the case of potash are similarly strikingly instructive and consistent, showing that the largest accumulation of manurial potash is in the surface soil, but that a very large proportion is also found in the second layer (nine inches) and even in the third layer. Dr. Dyer remarks that it would seem, on the whole, probable that when a soil in the surface depth contains as much as 0.01 per cent. of potash soluble in weak citric acid the special application of potassium salts, at any rate as far as cereals are concerned, is not needed. Dr. Dyer may be congratulated on the interesting results which he has brought to light by the application of a method which he suggested, representing as far as possible the conditions under which the plant gains nourishment from the soil. The more actively and practically the great question of fertilising the soil is approached the less will apprehension be felt as to the future wheat-supply of the world in spite of Sir William Crookes's well-known predictions as to the possibility of a nitrogen-famished soil.

#### RACIAL LONGEVITY AND LIFE INSURANCE.

THE statistics collected for American life insurance companies admit of comparisons which are not needed for the British insurance business. However divergent in origin, the British people have become sufficiently alike for the purpose of life insurance. In the United States, on the contrary, so large a proportion of the population have recently come from Europe that the question of original nationality is still a matter of practical importance. An English insurance company would not ask an applicant whether he was a Dane, a Saxon, a Briton, a Roman, or the descendant of a Huguenot refugee, and most persons would find it very difficult to answer such a question. In the United States, on the contrary, life insurance is founded on the longevity of the people of various countries and States. Statistics have shown that the Norwegians and Swedes have the longest lives. This is attributed not only to their general good physique but more especially to their freedom from digestive troubles. Mr. John F. Dryden, President of the Prudential Life Insurance Company of New Jersey, finds that the people who may be qualified as genuine

Americans have the longest life after the Swedes and Norwegians. Mr. Frederick L. Hoffman, the chief insurance statistician of America, states that the death-rate of persons under 20 years, and especially young children, is greater in the United States than in most European countries; but that after middle-age Americans live longer. He further claims that in spite of excesses committed in large towns people, as a whole, live a more temperate life in New England than in Old England. It is stated by these statisticians that out of every 10,000 children born in each of the four following States: 7551 will live to the age of at least 20 years in Sweden, 7201 in England, 7167 in Massachusetts, and only 5413 in Spain. The number that reach the age of 50 years, out of 10,000 born, are 6043 in Sweden, 5405 in England, 5275 in Massachusetts, and 3765 in Spain. The proportion in 10,000 attaining the age of 75 years is 2948 in Sweden, 2042 in Massachusetts, 1786 in England and Wales, and only 997 in Spain. It is claimed that sanitation generally has been much improved in America, that there is a wider diffusion of prosperity, and that the American people are made up of the best elements of the white races and that therefore the proportion of those who live beyond 50 years is greater. On the other hand, these conditions have not influenced favourably the negro race. Though they should be acclimatised—for the negro race has now inhabited America for some 200 years—the negro death-rate has nevertheless greatly increased, especially since the abolition of slavery. The fact is, that there is now less restraint on his tendency to debauchery and that the negro displays the most complete disregard for sanitary precautions. Perhaps these are but the first results of the emancipation of the slave; with time and the better spread of education he may mend his ways.

#### MEDICAL PLAYS ON THE FRENCH STAGE.

FOR some years past the modern stage has given more and more room to medicine in the subjects of which it treats. One or more medical men were often among the *dramatis personæ*, although as a rule they only played a secondary part. But to-day when authors are always on the look-out for original subjects and make the stage a pulpit from which they can preach with dramatic effect various theories dealing with human or economic sociology the leading character is a medical man or the whole point of the play turns upon some medical question. Soon after the extraordinary effect produced by Ibsen's *Revenants*, which treated of the influence of heredity, M. Brieux dealt with the same subject in his play *L'Evasion*, where he upheld the thesis, one not very strongly borne out from a scientific point of view, that the modern view which looks upon heredity as a sort of moral and physical prison from which the individual can never escape is false, and that the will, aided by some powerful motive—such as love, is sufficient to extricate the individual from his cell. Then came other plays, such as *En Paix*,<sup>1</sup> which dealt with the French Lunacy Law and *Les Remplaçantes* which showed the beauty of a mother suckling her child as against the vice of handing it over to a hired wet-nurse. Only recently three new medical plays came out, two of which have been produced while the third was interdicted by the censor. One called *Le Baillon* centres in the question of professional secrecy. A young girl suffering from tuberculosis is betrothed to a young man who asks her physician, Dr. A., as to her condition. Dr. A. refuses to give him any answer, as to do so would be a breach of professional confidence. The parties are married and later, when the disease has far advanced, a specialist, Dr. B., is called in who reproaches Dr. A. with not having prevented the marriage. Dr. A. repeats his argument and points out that Dr. B. has

<sup>1</sup> THE LANCET, Jan. 20th, 1900, p. 204.

himself written a book in which he upheld the theory that nothing whatever could justify a breach of professional confidence. So the play ends leaving the audience face to face with a difficulty which has been presented to them in the most forcible manner. The second play is a comedy the scene of which is laid in a little village. A girl who has been jilted by her lover suddenly falls into a state of lethargy. The lover to his great regret is forced to support the girl while in this condition. Little by little, however, the story of the sleeping girl gets wind and the village is thronged with curious visitors and committees of scientific inquirers. Thereupon the lover has the brilliant idea of making everybody pay a small fee to see the girl, when all of a sudden she wakes up quite well. But the lover begs her to keep up her slumber so that no one will lose the monetary advantages brought both to themselves and the villagers by the host of visitors. So she sleeps every weekday and wakes up on Sundays, with the result that the whole village becomes rich and she is enabled to bring a substantial dowry to her lover, to whom she is eventually united. The third piece, which has been prohibited, is called *Les Ararics* and has for subject the question of the dangers of the marriage of syphilitics. It was prohibited as immoral, although syphilis is not mentioned. But the play is dedicated to Dr. Fournier, Professor of Syphilography at the Faculty of Medicine and President of the Association for Promoting Sanitary and Moral Prophylaxis, concerning which our Paris Correspondent sent an account which appeared in our issue of Dec. 2nd, 1899, p. 1554. No one could mistake the subject of the piece, but its prohibition has been the cause of a lively discussion in the press. On the one hand, it is argued that a dramatic author should be allowed to present on the stage whatever subjects he likes, while others affirm that it would be harmful to morality to discuss so publicly such delicate pathological matters.

#### THE MANCHESTER AND SALFORD SEWAGE AGAIN.

MANCHESTER and Salford afford so marked an illustration of the suffering that arises from the neglect as well as the ignorance of old times that it should be noted well by all growing places. The Mersey and Irwell Joint Committee consider that Salford has been dilatory as to the treatment of its sewage and have decided "that the clerk be instructed to take such proceedings as would be necessary in accordance with the terms of the order of the court, dated July 9th, and May 23rd, 1898." One of the members spoke feelingly as to the Ship Canal never having been so filthy as during the past summer and of the immeasurable suffering from the filthy stench at Eccles, where "he had not been able to open his drawing- and dining-room windows for a week at a time." Manchester was dealt with more leniently, as it was considered "that the corporation were earnestly endeavouring to meet the wishes of the Joint Committee, and they recommended that the consideration of the position of the Manchester Corporation should be adjourned for six months." It is stated that in a few months more than half the sewage of Manchester will be dealt with on the bacterial system.

#### RUMINATION IN THE HUMAN SUBJECT.

In a long paper reprinted from *Il Policlinico* (Rome: Società Editrice Dante Alighieri) Dr. Silvio Silvestri of the Civil Hospital, Verona, has given an interesting account of a case in which of a family of six persons the father and three sons possessed the unusual faculty of rumination, whilst the mother and only daughter were normal in this respect. Several writers have already observed that the subjects of this peculiarity were most usually males from 10 to 20 years of age who suffered also from some neurotic condition such as

hysteria, neurasthenia, epilepsy, idiocy, or mental aberration. Dr. Silvestri's observations were made upon the three brothers above referred to, who were respectively 20, 18, and 15 years of age. Their family history showed a neurotic taint, for a maternal uncle had died insane, and the father was not only neurasthenic, but presented the phenomenon of rumination when a young man, whilst the mother had never exhibited any neurotic symptom and the sister of the young men although neurotic did not ruminate. The eldest brother was hypochondriacal, irritable, and incapable of mental work. Rumination commenced at the age of 15 years without any recognised cause and had continued up to the present time. His motor and sensory conditions were normal, as were also his organs of special sense with the exception of a slight diminution of the visual field; his knee-jerks were exaggerated; the other reflexes were normal. About 10 minutes after taking food he began to experience a sense of weight in the epigastrium and soon afterwards an imperative need to return the food to his mouth, a manœuvre which was more easy with solid and semi-solid substances than with liquids. The different articles of food returned to the mouth in the order in which they had been taken, so that the man had a double experience of all the flavours of a dinner. A powerful effort of will was generally capable of preventing the occurrence. During the first hour there were about 25 separate acts of rumination; then their frequency decreased and they came to an end about two hours after the food had been taken. With the second of the brothers, aged 18 years, rumination had existed for four years without being attributable to any known cause. With the third of the brothers, aged 15 years, it had existed for about two years. He said that he remembered distinctly that it commenced after he had fallen from a height of six feet, striking his thorax and epigastrium against a stone. Re-mastication of the food is an essential of rumination, which is thereby sharply distinguished from simple regurgitation. Dr. Silvestri has seen an instance of regurgitation in a man, aged 22 years, who for about the space of a year felt his food rise into his mouth some minutes after it was taken, so that he either had to eject it or if he was in company he swallowed it again without chewing it. The first rational explanation of rumination in the human subject was given by Dumur<sup>1</sup> who ascribed it to paralysis of the muscular tissue of the lower end of the œsophagus. Dr. Silvestri defines it as a motor neurosis of the stomach, the exciting cause of which is an abnormally sensitive mucous membrane, but the primary cause is cerebral or psychic (cortical). He gives references to about 27 memoirs on the subject and makes several suggestions as to treatment.

#### THE OVERLOADING OF HORSES.

ANYONE whose occupation calls him into any portion of London where there is much traffic cannot but be struck by the disgraceful manner in which horses drawing coal, timber, and other heavy goods are overlaid. The principle upon which owners go appears to be this: they ascertain how much a horse can draw in dry weather upon a smooth asphalt or wood pavement on the level. Regardless of the incessant changes of surface, whether due to inequalities caused by road-breakers, the vagaries of the weather, or change of level, they send their horses out in all weathers with a load calculated upon the rule which we have indicated above. Over and over again we have seen carters vainly endeavouring to get a perfectly willing horse attached to a heavy load up the steep ascent of Bedford-street. We wish to give the average carter every credit for the patience and gentleness with which he treats the horse in his charge, but it is not fair either to the man or to the horse

<sup>1</sup> De la Paralysie du Cardia ou Mérycisme (Diss. Bern., 1859).

that they should be called upon to perform impossible tasks. The sole reason why owners behave in this manner is due to a desire to save their pockets, but we should have thought that truer economy would be to use either more horses or to give out a lighter load. The municipal authorities are by no means blameless, for they keep the roadways very far from clean, while as to the sprinkling of gravel the lower portion of Bedford-street is apparently a sort of no man's land. The Strand is occasionally washed and fairly well gravelled. The upper part of Bedford-street is washed every day or so and gravelled when necessary, but the portion between Maiden-lane and the Strand, in which the declivity is steepest, is, as far as our knowledge goes, hardly ever washed or gravelled. Here is a good field for anti-vivisectionist activity.

#### THE CHEAP PISTOL ONCE MORE.
